## A JOURNAL OF ART, CIVIL ENGINEERING, AND BUILDING

### TECHNICAL EDUCATION BY GUILDS.

WO very remarkable governmental reports are before the public just now; and, although both are of such unusual gravity that they must be expected to fly over the heads of most of us, yet neither of them can fail to be studied by a large number of special readers, whilst those who are content to take them up less attentively in the form of the abbreviations given by the press may no doubt be spoken of as a very considerable proportion of the people at large. These documents, we need scarcely say, are,

first, the elaborate report, the second of a series, upon the subject of technical education, and, secondly, the equally exhaustive statement regarding the property of the old trade Corporations of the City of London. It may, at least, serve to point a moral as well as a paragraph if we say that the one deals with that most momentous question of the day, how to elevate the standard of specialist instruction for English artisans, whilst the other indicates the singular story of the accumulation of specialist funds for the promotion of guild-action in English manufacturing and trading industries, and the diversion of their revenues to strange purposes.

We do not propose to recapitulate now in any way the interesting information which is brought out in these two reports, but rather to suggest a line of thought, in relation to both of them, which, if it has not been wholly overlooked, has certainly not yet been allowed to acquire that prominence in discussion which we think there are many, especially of those who are connected with the more artistic branches of business, who may be inclined to think it deserves.

To begin with a plain proposition, we would ask the question why the always powerful agency of guild-action should not, amongst other measures, be made the subject of direct revival. If the Livery Companies of the ancient City of London have ceased to represent guild-action even in name, why should we not substitute for them new Livery Companies of the modern Metropolis, which, not only in name but in deed, shall answer to the urgent call of the working nation in these days for just that sort of furtherance of its industries which it is the reproach of the City Guilds that they have not in recent times occupied themselves in promoting? To take certain illustrations, let us point to the Goldsmiths' Company, the Merchant Taylors' Company, and the Fishmongers' Company. In the absurd condition, almost a mockery of their ancient aims, into which these Corporate Guilds have subsided—all being extremely wealthy, extremely hospitable, and little else—it is notorious that the chief public function of one of them is to give dinners to the Tories and that of another to give dinners to the Whigs; we do not at the moment care to remember what order of men it is who eat the turtle and venison of the third. But suppose the Goldsmiths' Company, in the first place, could be reorganised so as to rely chiefly upon the membership of the ornamental workers and their traders throughout London, or even throughout England, in gold and silver, brass and bronze, jewels, and the like; and suppose that such a body were led to establish a great guild, having for

its primary purpose the cultivation of artistic taste and refined craftsmanship in connection with the various departments of such exquisite business; need we inquire whether this is not exactly what the circumstances of industrial England at this moment demand? Preparatory schools, technical schools, advanced scientific schools, commercial societies, artistic societies, museums, laboratories, all suggest themselves readily to the fancy; and it is not too much to say that, with English money and English dexterity, a very moderate amount of exertion might place the cause of the highest artisanship, in these charming provinces of its wide dominion, in a state of prosperity which no other form of combination could accomplish, and which without combination it is hopeless to look for.

Turning next from the subject of artistic workmanship to such more strictly commercial manufacture as the Company of Merchant Taylors may be taken to represent, here again we cannot help inquiring whether a new and enlarged guild might not be made exceedingly useful in connection with the very extensive and important branches of English artisanship which deal with cloths and kindred fabrics. The most casual observer of the phenomena of London streets must have noticed within the last ten or fifteen years how largely the number of agents for provincial and foreign manufacturers of this class has been and still is increasing. Although we do not profess to have any right to speak of this particular trade, it seems not unreasonable to suppose that the interests involved must be rapidly developing. If so, then the considerations connected with advanced intelligence and skill must be becoming more and more urgent in their demands for the united action of experts in the direction of commercial and scientific education and an interchange of technical inquiry and opinion; and for this, we say, guild-action must be the most favourable agency.

Nor do we pause in accepting, thirdly, the wealthy Fishmongers' Company as representing still another form in which guild-action might be made of immense service to the commonwealth. Here, of course, we are still more out of our professional field; but if even only a part were true of what has of late years been laid before the public in reference to the urgent need for a practical application of science and scientific organisation to the great department of national industry here in question, it must be almost unnecessary to suggest whether the foundation provided by the obsolete City guild might not be built upon, in this as in other cases, so that the highly useful element of guild-action might be re-established in modern form to meet modern needs.

But we may rest content with the general application of these more notable examples, and now turn to our own more favourite province, the truly noble field of building and structural decoration, which employs so large a proportion of the population in its service, and awakens so gracious an interest in almost every member of the community. So far as we know, the City Livery Companies connected nominally with such industries are comparatively weak and poor, but still the importance which they might be made to assume in the world of English artisanship no one will deny, and we will therefore venture to suppose a great building guild to be established by the help of some such general rearrangement of funds as would no doubt be more or less necessary for the reorganisation of various other guilds besides. Here again the same proposals have to be offered for the application of guild-action to tech-

nical education, but happily the precise forms and purposes are already well understood, and the actual work is going on in all parts of the country, although frequently under disadvantages. We need not observe that it is in this species of artistic study, taken broadly, that the Government has been chiefly operating, and that the local schools of design are doing their work diligently. But even in a department like this it seems fair to argue that guild-action would be better than State-action. We hear a good deal just now about the comparative merits of localisation and centralisation, but if there be one thing more than another with reference to which the benefits to be derived from centralised organisation must be recognisable by everybody, it is the specialist cultivation of technical knowledge and skill. The time is long gone by since the inauguration of the system of Great Exhibitions put a stop once for all to the affectation of sedate secrecy with which here and there an old-fashioned house of business might flatter itself into the belief that the world was not able to move without its permission. It was surprisingly soon discovered that, when all the world began comparing notes, the question that arose was, not how to confine and localise, but how to extend, expand, and embrace enough, how to be sufficiently comprehensive and sufficiently centralised. The Government schools of design are based upon this idea, comprehending in their action the largest accessible circumference, and concentrating their administration upon the simplest governing authority. But it is considered to be one of the leading faults of the South Kensington system that this concentration or centralisation always focuses in a red-tape-tied governmental bureau, and never seeks in guild-action the vitality, or particular technical intelligence, which that alone can supply. What would the Royal Academy be if it were placed under the control of a department of the Government? What, therefore, might the public schools of art and science become if they were administered by national guilds of the artistic and scientific craftsmen of this great commonwealth of industry?

The two points we submit are these—that the next step in English industrial progress ought probably to be the institution of national guilds for technical education and culture; and that it might perhaps be well to utilise the old City guilds, and of course their revenues, in the establishment of these as their modern successors. The readiness with which several of the ancient livery corporations have of late come forward spontaneously for the endowment of technical schools proves two things—first, that they still possess a corporate instinct or conscience which takes this direction; and, secondly, that their public spirit may still be relied upon. We do not take the liberty of dictating to those who have the case in hand either on one side or on the other, but we cannot help thinking that we have suggested a way of dealing with a great and interesting problem which is better than the adoption of measures which would divert to outside aims, no matter how good in themselves, funds which in their own original object have a special purpose to serve whose promotion is one of the most urgent demands of the day.

## FIRST IMPRESSIONS OF GLASS-MOSAIC.

By LEWIS F. DAY.

IT is only in its place, and, moreover, in the mass, that glass-mosaic is seen to advantage. It is, therefore, not until he gets as far as Italy that an Englishman can form any true conception of its decorative value, and then it is a sort of revelation to him. But it is only by degrees that the message of colour is revealed, presuming him to travel by the ordinary route, which a novice does well to follow; for by going off the beaten track he sacrifices time and comfort to worse than no purpose. In the frequented cities there is more to see, and more worth seeing; he cannot by any possibility exhaust the mines of art. Everywhere he may have the gratification of digging out his own examples, prized the more because they were obscure.

The first impression produced by mosaic such as that one sees, for instance, at Milan, in the church of St. Ambrogio, where there is a half-dome of early mosaic, is that it is hideous. Again, in the church of St. Lorenzo in the same city there is a chapel not so much decorated as disfigured by mosaic, in which, if there was ever any colour, the colour has gone, leaving a blackness certainly not beautiful. One begins

to think that the Philistine is right, and that the boasted permanence of this mode of decoration is its crowning sin. No one would contend, of course, that such mosaic as this has any claims to other than archaeological interest. But even in such important instances of decoration as that of the dome of the Baptistery at Florence, the perfection of the mode is not very apparent. The glory of the art is not yet revealed. You are rather impressed by the solemn gloom of the interior. It is only on a very sunny day at noon that the design is completely visible; and even then one has to persuade one's self into the belief that it is beautiful either in colour or design. The effect is generally at the best sober, even to dullness; and it is only in that section of the dome immediately facing the open door, and in the soffits of the windows, which catch the light of the sun, that you get any glint of gold, to say nothing of that golden glory which is so characteristic a charm of mosaic.

Yet even here, in the decoration of the apse, one begins to suspect what possibilities there may be in mosaic; and, again, in the arabesque, which covers the upper portion of the dome, compared to which the figures below are dull and colourless. It is doubtful if even more light would reveal colour in these subjects; but it would be rash to say what might not be brought out by brilliant illumination. It will explain how little the mosaic impressed me if I say that the inlay of the pavement, simple as it is, struck me as eminently more satisfactory decoration in its way. It is that I carried away in my recollection of the baptistery, not the mosaics of the dome.

When we arrive at last at Venice, the glory of the art dawns upon us. No one in the slightest degree gifted with the perception of colour fails to be impressed with the gorgeousness of the interior of St. Mark's, and no one who cares to analyse the source of his delight can fail to see that it is very greatly dependent upon the mosaic decoration of walls and vaults. To inquire still further into the cause of this overpowering splendour is to discover that it is mainly to the glory of gold that the effect is to be attributed. Everywhere a ground of gold is adopted, for pictures and ornament alike; and, more, the decorative value of the mosaic appears to be in direct and exact proportion to the mass of this golden ground. Some of the later pictures, with their closely-packed figure groups and pictorial accessories, fail altogether in effectiveness; whilst the stiff and archaic figures of Byzantine character, which are in themselves not beautiful either in design or colour, form the most magnificent decoration. Happily, the golden ground prevails. In the best work the colour is never more than as one to three in proportion to the gold. In many instances as much as five-sixths of the surface is of gold, so slightly do figures and ornament encroach upon it. Had this golden ground been simple gilding there might have been too much of it; but there is a quality of its own about this brilliant but broken surface, where every variation in the angle at which the cubes are set tells, so that the very irregularity prevents anything like monotony of colour. In the lightest spots there are tesserae which do not catch the light; and in the shade are corresponding ones which sparkle unexpectedly and light up the shadows. It is this unexpectedness, resulting from the uneven, broken surface of mosaic, that gives it its most charming characteristic; and it is in the gold more than in the colour that this charm is to be found. It must be confessed that even at St. Mark's the draperies of the early figures are still too even in colour, and that the variations of tint which do occur are often much too sudden. That is to say, the shadows of the draperies are mostly too heavy and the high lights too white, whilst heavy shadow, high light, and intermediate local tint, are each in themselves too flat. This may be due in part to the effect of time upon the work, or to restoration; in either of which cases the boasted permanence of mosaic is not all that it has been vaunted. However that may be, one has a right to expect, in a medium which lends itself to such fascinating variation of tint, something more of variety and beauty of colour.

Leaving Venice with a very distinct impression of the predominant value of gold in mosaic, the first sight of the churches of Ravenna is a second revelation, not less wonderful nor less impressive than the first. From church to church your wonder grows, until you realise at length all the possibilities of colour that lie in the hands of the mosaicist. The value of the gold ground is too obvious for the Ravennese artists to have ignored it, and they have adopted it freely, as, for example, in the baptistery of St. Maria in Cosmedin, where the dome is decorated with figures of the Apostles, draped in

white, on a gold ground. But even in this white and gold there is more colour than in similar Venetian work. Here the folds of the drapery are not preternaturally pronounced. Instead of heavy shadows and forced high lights, there is a silvery or pearly tint pervading, and altogether a delicacy of effect that one had not been led to expect in mosaic.

In the decoration of the dome of another baptistery (*the Baptistery*) a very similar design has been adopted, but this time on a coloured ground. The Apostles are represented again in white and gold, but on a lightish and brightish blue background, the space between them broken by arabesque ornament in gold. Above are suspended pearly white curtains, which hang from the rim of the central medallion, and form a sort of pattern about their heads. They tread the green earth in a rather active, not to say violent, manner, in which is no suggestion of conventional stiffness. Below all this is a rich frieze of architectural and emblematic design, connecting the pictured dome with the lower walls. These are decorated with very beautiful foliated scroll work in olive and gold on a deep indigo blue ground, in the midst of which are occasional medallions, with panels in white, on a ground of gold. Here, indeed, is colour as beautiful as one could wish. In the gold it appears that two kinds are used, the one more coppery than is usual.

The mosaics of the church of St. Apollinare Nuovo, which, like those at the baptistery of St. Maria in Cosmedin, are said to date from the sixth century, are like them in delicate colour on a gold ground. The nave is one mass of mosaic. Here, again, the figures are designed in processional order; on the south side a series of saints, on the north a band of virgins, twenty-two in number, all in white and gold on a golden ground. There is no confusion resulting from this pervading gold, for the golden draperies are distinguished from the ground by being diapered with delicate patternwork in colour, which gives a glow to the metal. The effect is sometimes as of variously-tinted gold.

The individual figures are separated one from the other by palm-trees, the trunks of which give valuable vertical lines in the composition, whilst the fronds diaper with sprays of green the space "to let" above. The plain gold nimbus about the head of each is edged with a rim of white and red. The grass about their feet is green, the whole resulting in a general effect of green and white and tinted gold, singularly pure and bright and beautiful. The corresponding male saints are less interesting.

In the decoration of the chapel of the Episcopal Palace a blue ground occurs again; and there is also an instance of a figure with golden drapery, shaded with brown, on a ground of gold, the effect of which is excellent, and not in the least confused. In the mausoleum of Galla Placidia the greater part of the mosaic is on a deep blue ground. In the diapering of the vaulting the pattern, as rich as it is bold, is all in pale blues and greens on deep blue, with only a small amount of gold introduced. The scrolls in gold are very bold and strong in design, and the borders, whether of geometric or foliated design, are equally happy. One of these borders consists of a wreath of foliage and fruits in colour, on a ground of white. The golden ground of another (fret) border is made up of alternate tesserae of gold and golden-brown.

Beautiful as these mosaics are, they are not richer than those at St. Vitale, where the entire effect of the choir is one of exceeding splendour. Here is, indeed, a depth and fulness of colour almost beyond conception—quite beyond description. Very noticeable is the abundance of rich dark blue and brilliant green, the latter occasionally being adopted for a background; as in the cupola, whose four divisions are decorated with scrolls alternately of green on gold and of gold on green, on the principle of counter-change. Some of the richer panels are framed in borders of subdued tints, where the colour is confined, in fact, to simple combinations of black and white and Indian red, forming a perfect foil to the gorgeous pictures and patterns they enclose.

Of the design of these mosaics it is not my purpose to say much, though, indeed, they might be taken as the text for a discourse on decoration, and more especially of dome-decoration. A certain quaintness is to be observed in some of the figures, but seldom anything like stiffness. On the contrary, there is a surprising breadth and freedom about the design, and an equally unexpected absence of the bogey-like attributes common to Byzantine figure work. The medallion heads of virgins in the chapel of the Episcopal Palace seem as

if they might fairly represent so many ladies of the eleventh century. Architectural accessories are represented sometimes in a manner that is naïve, but not otherwise than decorative. Foliage, such as that of the vine, is drawn almost naturally in some of the scrolls; the arabesques are vigorously designed; the diapers are varied and interesting; and the monotony of ornament is relieved by the judicious introduction of birds, animals, and other creatures, which serve at the same time some symbolic purpose also. And though the examples range over a period of some six or seven centuries, it is not very apparent to the mere artist which examples belong to which date. Occasionally one recognises an early instance, but only an antiquary could honestly pretend to determine at once from internal evidence the precise period to which the various mosaics belong. For my own part, I confess that I was content to take what the guide-book says for granted on that score, and confine myself to the study of their artistic merits.

Whilst on the subject of confession, I may admit that my silence with regard to the mosaics at St. Apollinaire in Classe is due to the fact that I did not get out to see them. There is so much to see in Ravenna, and the hotel accommodation is so little inviting, that I succumbed to the cravings after wholesome food, and left that much unseen. All the same, I hope to go again some day and revive my impressions of these masterly decorations. It is a joy to see them. It is not even as at St. Mark's, where the grandeur of the whole so impresses you that it is long before you can descend to the critical examination of details. At Ravenna the interiors are so many gems, set before you to see and to enjoy; and, if you are of that mind, you have only to look and learn.

## THE BRITISH MUSEUM.

THE annual reports of the officers of the British Museum have been published this week. The principal librarian says that the removal of the natural history collections to the new museum in Cromwell Road having been completed, the rooms in Bloomsbury in which the zoological collections had been exhibited have been applied to the accommodation of the departments remaining there. This has enabled the keeper of the department of Oriental antiquities to make a more extensive exhibition of Egyptian objects of various characters in a system of instructive classification: the ancient vases and terra-cottas, the bronzes, and the ancient paintings have been rearranged and more fully displayed by the keeper of Greek and Roman antiquities; British and Mediæval collections have been placed on exhibition; the glass and porcelain collections have been brought together in one room; and an extensive ethnographical collection, including the contents of the Christy Museum, transferred from Victoria Street, is in process of geographical arrangement in the long gallery formerly occupied by the collections of birds. In the gallery lately occupied by the British Zoological collection, coins and medals of all countries, together with photographs of drawings of the old masters, and of early engravings of the Italian and Flemish schools, have been exhibited. Instructions have been given to keepers of departments to put aside duplicate objects and specimens for the formation of a collection to be lent for exhibition in the provinces.

Owing to the refusal of the Porte to renew the firman under which excavations for antiquities have been carried on since the year 1873 in Assyria and Babylonia, these works have been discontinued; and, with the assistance of Her Majesty's consuls at Mossul and Baghdad, arrangements have been made for protecting as far as possible from encroachment the sites opened in the neighbourhood of these cities, including that of the ancient city of Sippara, only partially explored, but with important results. A subscription fund having been raised for renewing excavations on the site of the Temple of Diana at Ephesus, under the direction of Mr. J. T. Wood, the trustees of the Museum have consented to his occupation of the site for this purpose, and the work of excavation has been proceeded with.

During the year 36,046 volumes and pamphlets have been added to the library (including books of music and volumes of newspapers), of which 2,692 were presented, 10,612 received in pursuance of the laws of English copyright, 1,474 received under the international copyright treaties, and 20,350 acquired by purchase. Also 47,605 parts of volumes (or separate numbers of periodical publications and works in progress) have been added, of which 1,091 were presented, 25,664 received in pursuance of the laws of English copyright, 709 received under the international copyright treaties, and 20,141 acquired by purchase. The number of sets of newspapers published in the United Kingdom and received under the provisions of the Copyright Act during the past year has been as follows, viz., 390 published in London and

its suburbs, 1,117 in other parts of England and Wales, 179 in Scotland, and 150 in Ireland: 58 volumes, belonging to 21 different sets, have been purchased; and 1,608 numbers have been presented. In addition 6,378 pieces of music have been acquired, each piece complete in itself, of which 3,314 were received by English, and 2,620 by international copyright, and 444 by purchase.

The Stowe Collection of MSS., the purchase of which from the Earl of Ashburnham was sanctioned by Parliament at the close of last session, consisted of 996 volumes and sets of volumes, as numbered in the catalogue. Of these, 95 numbers, viz., the MSS. in the Irish language, and certain volumes specially relating to Ireland, were, by order of the Government deposited in the library of the Royal Irish Academy in Dublin, the rest being assigned to the British Museum. Among the collections relating to English history are:—Forty-two Anglo-Saxon charters, dating from A.D. 693 to the eleventh century; a wardrobe book of Edward II., 1322–1323; wardrobe and jewel accounts of Elizabeth; correspondence of Sir Thomas Edmondes, Ambassador in France and the Low Countries, *temp.* Elizabeth and James I., in 12 volumes; correspondence of Arthur Capel, Earl of Essex, Lord Lieutenant of Ireland, *temp.* Charles II., in 25 volumes; correspondence of the Court of Hanover with political parties in England, early in the eighteenth century, in 10 volumes; letters of the Duke and Duchess of Marlborough to Secretary Craggs; various diplomatic and literary correspondence; minute-book of the Privy Council, 1661–1670; and several separate documents and letters of interest. MSS. of value for English literature and topography are:—A Latin Psalter with Anglo-Saxon glosses of the eleventh century; the register of Hyde Abbey, Winchester, with finely-executed drawings by an English artist of the eleventh century; a volume of English homilies, of the end of the twelfth century; Lives of Saints in English verse, of the fourteenth century; Gower's "Confessio Amantis," fifteenth century; and several chartularies of English monasteries, from the twelfth to the fifteenth centuries, including the Boldon Book of Durham, a register of St. Thomas, Southwark, and a corporation register of Winchester. There are also several heraldic MSS., comprising the collections of Anstis, Garter, and various county visitations.

The department of prints and drawings has been presented with 965 examples. Among them are five separate donations by Mr. R. P. Cuff, of his own engraved works, amounting to 134 prints, and including interesting proofs of the illustrations to Ruskin's "Modern Painters," "Stones of Venice," and "Seven Lamps of Architecture;" views of the Houses of Parliament; the interior of the building erected for the Exhibition for the Industry of all Nations, 1851, &c. Five donations by Mr. J. Deffett Francis, consisting of twenty-four prints and drawings, and including a large study by Richard Cook, R.A., for one of his illustrations to Scott's "Lady of the Lake," together with the pencil drawing of the same subject executed for the engraving, and a proof of the plate engraved by Cosmo Armstrong, which has sketches by Cook in the margin. A collection of finished drawings and sketches, 294 in number, executed by Charles Alfred Stothard, for his work "The Monumental Effigies of Great Britain." Thirty drawings of Hindoo gods, from working drawings in a temple in Ceylon, presented by Andrew Nicoll, R.H.A. "Impressions from a collection of wood-blocks used in the printing of chap-books, children's books, &c., in York, Leeds, Hull, and other towns of Yorkshire, during the last and the first half of the present century. Privately printed 1870," presented by Mr. W. J. Linton. The cast of Shakespeare's face, taken after death, engraved on wood by W. J. Linton from a drawing by W. Page. Fifteen etchings by Professor A. Legros. A tracing of the earliest wall painting known to exist in Japan, dating in all probability from the seventh century of our era. Among the purchases are a very fine and extensive collection of Chinese and Japanese drawings and paintings brought together by Mr. W. Anderson, 128 examples of the Italian school, 544 of the German school, 59 of the Dutch and Flemish schools, 354 of the French school, and 277 examples of the English school.

Mr. Newton in his report says it is much to be regretted that no provision has yet been made for the exhibition of the sculptures still withdrawn from public view in the sepulchral basement. This collection, which contains part both of the Elgin and Towneley marbles, has already suffered much from exposure to the foul atmosphere of the basement; and the detriment to the surface of the sculptures will be aggravated year by year till a proper room is provided for their exhibition.

Among the acquisitions in his department are six ancient mural paintings, representing (1) Pluto carrying off Proserpina in a quadriga; (2–3) two groups of a male and a female figure; (4) a winged female figure holding a branch; (5) a male figure holding a *calathus*; and (6) a flower. These paintings, which originally decorated the tomb of the Nasones, discovered on the Via Flaminina in 1674, had been lost sight of for more than a century, until they were purchased at a sale by Mr. George Richmond, R.A. They are remarkable for free and vigorous drawing, and for the rich and mellow tone of their colouring. They formed part of the series of paintings which is engraved in Bartoli, "Pittura antiche del sepolcro dei Nasonii," published 1680.

## THE BELGIAN SYSTEM OF ART EDUCATION.

A PAPER was read on Saturday, at the City and Guilds of London Central Institution, by M. de Taye, Director of the Academy of Fine Arts at Louvain, on "Artistic Instruction in Belgium and its Applications to Industry." The author began by referring to the anxiety of all nations in the present day to develop the technical practice of trades by popularising the teaching of drawing. The late Prince Consort endeavoured to cultivate the national taste in this country, and to show that beauty must be placed before cheapness in all artistic industrial production. As Count Laborde wrote in his remarkable report on the Exhibition of 1851, "Art is the most powerful engine of industry." Of the three countries which had specially busied themselves with the solution of the problem of popularising art teaching, France had shown a subtlety of æsthetic sense, England a powerful spirit of organisation, while Belgium had proceeded with a well-considered method founded on its brilliant traditions. Describing then what had been done in Belgium, he said that in the field of primary education they had first to do away with the copy drawing which was everywhere working out its evil tendencies. Copying taught nothing. The pupil thought he had learnt to draw, but after practising in that method for four or five years he was scarcely able to represent a solid. The antidote to copy drawing was sought in drawing from the relief. In their primary schools, in order to train the eye and the hand of the pupil, they had arranged a course of freehand drawing, in which there was a direct application of the principles of plain ornamentation. This was in accordance with the method approved in Germany, where methodology had been studied with great success, and it proceeded on the lines laid down by the learned Herr Von Müller, Minister of Public Instruction in Prussia, who declared that in the Real-schule they should try not so much to make artists of the pupils as to make them understand the utility of the knowledge and practice of the language of form. After freehand drawing came the use of instruments for the expression of the more complicated geometrical forms on paper. The application to ornament being continued and developed served to prove the direct practical usefulness of the exercises. These two courses enabled the pupil to begin with advantage the study of relief—the victorious enemy of the copy. Projection was taken first, perspective afterwards, the first principles of the study of projections forming the basis to the study of the appearance of objects. From these elementary exercises the pupil passed to the drawing of solids. When, added to this, the pupil knew perfectly the characteristics of the laws of harmony and contrast in colour, he possessed quite sufficient artistic ideas to begin the ordinary work of life; and whatever profession or calling he might enter upon, that which he has thus learnt, and the familiarity with the practical notions of the language of form, would be of use to him, whether he first passed through schools of higher grade or went direct from the primary school to the workshop. In conclusion, M. de Taye maintained that the introduction of drawing in the primary schools of Belgium had increased the wealth and well-being of the working population; while by refining the taste of the nation it had proved a powerful element of progress in a moral, material, and intellectual point of view. Sir Philip Cunliffe Owen, who moved a vote of thanks to M. de Taye for his paper, expressed a hope that the wish of His Majesty the King of the Belgians to see museums, such as that at South Kensington, established in Belgium, and opened in the evenings for the benefit of the industrial classes, would soon be accomplished.

## NATIONAL COMPETITION REPORTS.

THE number of works sent up from schools of art for examination in 1883 was 226,415, from 192 schools of art and branch classes. Of these works 926 entered into the National Competition, for which the examination occupied seven days. The following are the reports of the examiners who adjudicated on the various stages of instruction submitted to them on each day.

*Drawing and Painting the Figure from the Antique and from Life; Studies of Drapery.*

(Examiners:—E. J. POYNTER, R.A.; H. S. MARKS, R.A.; W. F. YEAMES, R.A.)

The gold medal for the antique was awarded to a drawing of a faun carrying a kid, from the Hanley School of Art, of excellent workmanship and careful finish, without excessive labour, in which the spirit and grace of the original were well rendered. These valuable qualities atoned for certain faults of detail, of which the smallness of the feet and defective drawing in the left arm were the most noticeable. An extra gold medal was given for a drawing beyond the prescribed size submitted from the South Kensington School of Art.

The gold medal for the study of the figure from life was also awarded to a student of Hanley School of Art for good and accurate drawing and careful finish of a graceful and easily-posed figure.

In many drawings and paintings of the figure from the antique and from life the examiners observed an incompleteness in representing the extremities. Some studies of the figure from life were made from models of defective development and manifestly disproportionate limbs. Such examples are misleading, and the master should make every effort to obtain better models for the students. As this is in some places a matter of difficulty, such studies should be supplemented by work from good casts taken from well-formed natural subjects. The student training his eye to see correct proportion in such casts would avoid a failing which is usual, namely, exaggeration of disproportion, whereby the student may try to obtain what he considers to be individuality in his work.

The competition for the gold medal offered for paintings of drapery was limited to a very few studies, the best of which, from Nottingham School of Art, was rewarded with a silver medal. The examiners would desire to see a greater number and better studies in this stage. Paintings of the antique figure in monochrome were fewer in number and poorer in quality than on previous occasions.

*Modelling the Figure from the Antique and from Life, Details, Designs, &c.*

(Examiners :—E. J. POYNTER, R.A. ; J. E. BOEHM, R.A. ; W. F. YEAMES, R.A. ; H. THORNYCROFT, A.R.A.)

The number of works submitted was above the average. Many, however, were very poor in execution, and should not have been passed by the masters of schools as specimens worth sending up for examination. In future none but works in plaster will be admitted as eligible to compete for the gold medal. The majority of figures modelled from the antique were from the *Hercules with the Apples*, the muscular developments of which were absurdly exaggerated in some of the studies. A book prize alone was awarded in this stage. This antique figure is scarcely one to be recommended for the use of students. Its mannerisms are apt to be misunderstood. The gold medal for modelling the figure from the life was awarded to an admirably expressed semi-recumbent figure from the South Kensington School of Art.

The models of heads in many cases lost value from want of careful study and thorough workmanship. As a rule, the chief attention had been paid to the face alone, to the neglect of the neck and the back of the head. Others which gained awards were modelled from subjects lacking distinction of form. Higher awards in these cases were withheld because the students had not attempted to carry out their works with that delicacy and refinement of execution to which moist clay so especially lends itself. Still, it is worthy of notice that in a few models from the nude, especially those by students at the South Kensington schools, action was well felt and expressed, and this imparted interest to the work. Greater attention should be given to the modelling of extremities in studies from the figure, and in models of foliage, &c.

A gold medal was awarded to Sheffield School of Art for a pair of admirably modelled wax panels designed for cast metal work.

A few beaten and engraved metal works and carved wooden chairs were submitted. It should be understood that such works are considered merely in respect of their design and modelling, and not for merit in respect of technicalities in process. In future, articles of furniture, like chairs, should not be sent up to London for examination.

An imperfect acquaintance with the rules which regulate the arrangement of mouldings and other details was noticeable in almost all the modelled designs for doorways submitted for the Plasterers' Company's prize, and the highest award in this stage was a silver medal.

*Architectural Designs and Drawings.—Studies of Historic Ornament.*

(Examiners :—E. J. POYNTER, R.A. ; G. AITCHISON, A.R.A. ; J. J. STEVENSON.)

The gold medal was awarded for a set of designs for a cathedral from Lambeth School of Art,\* and a silver medal was given for a set of designs for school buildings and chapel from the South Kensington School.

The design for a cathedral was mainly noticeable for the width of its nave opening into the larger square covered by the dome. The angle piers of the transepts projected so little that they hardly intercepted any of the view, and the cupola was not too high above the pavement to be well and easily seen, while its form kept pure, showed that the author had grasped the idea of what was wanted and carried it out.

The designer of the school buildings and chapel had fairly considered the subject, and well-proportioned some of the parts and well-balanced their filling in. He had also carefully drawn and neatly finished the whole set. Both these sets of drawings were well executed and thoughtfully carried out in detail. The latter, though not quite up to the standard which should have gained it a

gold medal, was thoroughly studied as regarded its requirements, and was of more practical value to a student than the first-named set of designs for a cathedral.

*Designs for Textiles, Carpets, Lace, Silk, Printed Muslins, Cottons, Woven Hangings, for Pottery, for Tiles, Mosaics, &c.—Studies of Flowers for Ornamental Arrangement.*

(Examiners :—E. J. POYNTER, R.A. ; WM. MORRIS ; W. CRANE.)

Silver medals were awarded for two good adaptations of Persian designs for carpets. The imitation was, however, very close, and the study of the original examples has been directed to the details of form and colour rather than to the adaptation of the general principles which regulate the harmony of Oriental carpets to patterns requiring some invention on the part of the student. There were many instances of mixture of geometric and naturalistic plant forms and flowers which produced abrupt contrasts. The examiners remarked that students who submit designs for carpets do not always comply with the rule requiring them to execute a portion of the design to full size upon squared paper. This omission acts to the prejudice of the students, and masters of schools of art should, as far as possible, prevent its recurrence. One design, for instance, which seemed to show more originality than the others, had to receive a lower award in consequence of this omission.

The number and quality of designs for lace were below the average. A silver medal was given for a design for Devonshire lace from the Exeter School of Art, showing originality in spite of some awkwardness in the arrangement of leading forms. As regards the class of designs, especially from Nottingham for machine-made lace curtains, the examiners observed an almost stereotyped scheme of ornament, involving a broad border and an inner area of lavish pattern. In future it is desirable for students to draw to full scale a portion of the patterns for lace curtains they send up. The study of flat Flemish pillow lace of good scroll pattern is also recommended to the designers of this class of goods since the mechanical imitation of the raised and compact work in needlepoint laces does not appear to have reached as successful a standard as that of the imitation of flat pillow-made laces. The designs for hand-made laces were not as good as in previous years.

In the class of designs for woven silks the designs rewarded showed an advance, and a gold medal was awarded to the Macclesfield School of Art. The styles of the late seventeenth and eighteenth centuries appear to have been too exclusively studied and over closely imitated.

The examiners considered that the designs for tiles, for which the gold and a silver medal were awarded, were far above both the ordinary trade patterns and the designs usually sent to them for examination. They showed remarkable taste in the selection and treatment of colour, and in the case of the design for which the gold medal was awarded the construction of the pattern for repetition was well worked out.

As usual, the studies in stages 14a and 22a combined were numerous ; but botanical analysis—that is to say, the dissection of plants or the mere diagrammatical treatment of plant forms as hitherto practised—does not in any way tend to give the student an appreciation of their characteristics for decorative purposes. The examiners advise, therefore, that it should be discontinued and the study of flowers and plants directed to the understanding of their beauties of form and colour, and their suitability for ornamental treatment and for their necessary adaptation to that end.

The examiners were surprised to find that the important class of designs for printing upon cotton and other fabrics was scarcely represented, and that the few examples sent up were, with one exception, the silver medal award to Manchester (Cavendish Street) School of Art, very indifferent.

*Designs for Wall Papers, Furniture, Metal Work, &c.*

(Examiners :—E. J. POYNTER, R.A. ; WM. MORRIS ; W. CRANE.)

The examiners were pleased to find a distinct improvement in the use of colours for wall papers, and a gold medal for a set of designs for wall papers and furniture coverings was given to Leicester School of Art. On the other hand, they felt that, having regard to its widespread manufacture, the absence of designs for furniture was conspicuous.

In the section of metal work a silver medal was awarded for a frame in the Renaissance style, though it showed the characteristics of a style more adapted for carving in wood than for beaten metal work. Amongst the designs for cups, vases, tazzas, centre-pieces for tables, and such like, there was a fair average of good execution, but a too exclusive resort to a well-worn style more suitable to architectural sculpture than to such comparatively small articles.

*Painting from Still Life.—Flowers and Monochrome Studies of "Tone" and from Casts, &c.*

(Examiners :—E. J. POYNTER, R.A. ; G. D. LESLIE, R.A. ; W. F. YEAMES, R.A.)

The competition of paintings from still life was remarkable for the amount of good work which it brought together. Examples in

\* This award was subsequently withdrawn, as the drawings were not wholly executed in the school.

which coarse treatment was noticeable, as in works of previous years, were fewer in quantity this year. The excellence of the realism, so marked a quality of the large studies done by the students in training and national scholars of the National Art Training School at South Kensington, appears to the examiners to have been carried so far as almost to counteract the practical utility which such realism in painting can be to decorative art generally.

The gold medal was awarded to a painting, from the Brighton School of Art, of some tiles, antique bronzes, and a bulrush tastefully arranged before a background of Assyrian sculpture. The qualities of the different materials in this composition were correctly imitated, although the background had an artificial appearance; the method of painting was thoroughly sound.

In the class of water-colour paintings a gold medal was given for a work, from the Hull School of Art, of very high technical completeness, painted, however, from a group of not very well-chosen materials, the inharmonious effect of which was increased by somewhat awkward arrangement. The examiners' previous remarks as to realism apply with special force to this water-colour painting. The Female School of Art, Bloomsbury, gained the rather exceptional award of a gold medal for water-colour painting of flowers and fruit without background, which class was well represented.

In the useful stage of monochrome painting of ornament from the cast many awards were made. But one work for study of "tone" carried out the views which the examiners had when they recommended this branch of art study in their reports upon the two last national competitions. A bronze medal was given for this work, which came from the Birmingham School of Art.

#### *Mechanical Drawings and Drawings from Measurement.*

(Examiner: Professor UNWIN.)

A silver medal was awarded for a set of three drawings, from the Dundee School of Art, of a complicated piece of machinery showing exceptional power of accurate projection and very artistic feeling in the rendering of the work. A bronze medal was awarded to a set of drawings of machine construction from the science class, College Street, Swindon, which were of a good style for working drawings. The lining was clear and sharp, and sectioning and colouring were good. A national book prize was given for a set of twenty drawings of building construction from Peterborough (Class No. 2,694) by a young student whose progress appeared to give evidence of attention to careful instruction. Many of the drawings were executed with extreme neatness. The set, which embraced brick, timber, and metal details, showed care on the part of the teacher in directing this useful course of instruction. On the whole, the mechanical drawings were somewhat better than those submitted last year, but the number which could be selected for national competition was very small.

### LANCASHIRE AND CHESHIRE ANTIQUARIAN SOCIETY.

THE members of the Lancashire and Cheshire Antiquarian Society took part in an archaeological excursion to Lancaster and the neighbourhood on Saturday last. On their arrival in Lancaster, the party proceeded under the guidance of Mr. E. B. Dawson and Mr. W. O. Roper to visit Lancaster Castle, and all parts were examined from the dungeons to John of Gaunt's chair. The dungeons are underground and are entirely destitute of light, the roofs have been formed by placing cement over a wattled framework, and though no vestiges of the sticks now remain, the impress of them can be seen on examination. The mass of plaster would in time become almost as hard as stone. In these damp dens of more than midnight blackness the unfortunate prisoners were chained to iron rings in the floor. The buildings of the castle exhibit great variety of style owing to the different periods at which they had been erected, and the various modifications made necessary by their modern uses. Little visible remains of the Roman structure, for Lancaster suffered more even than the other stations from the attacks of Danes and Scots, and by the time of the Conquest was a mere village in the manor of Halton. When Roger of Poitou began to build his baronial castle, he doubtless incorporated in it as much of the Roman walls and towers as he found to be of use. From the charter he gave to the priory of his foundation, we know that the "Old Wall" was the name even then given to the remains of the Roman fortress. The Norman castle with many subsequent additions was the scene where King John received the homage of the Scotch king for such territories as he held of the Crown of England, and here John of Gaunt and his son Henry IV. held their courts. In the sanguinary struggles of the Wars of the Roses it was now in the hands of one party and now of the other, and on one occasion gave shelter to Edward IV. It has also been visited by Charles II. and by the present Queen of England, who, in addition to her other titles, is entitled to that of "Duke" of Lancaster. After a prolonged examination of the architectural and other points of interest, Mr.

W. O. Roper called the attention of the visitors to the fine Roman altar which was found when the foundations of the Shire Hall were dug. This has an inscription which shows that it was dedicated by Vibinius Lucius to the god Mars Cocidius. It is supposed that Cocidius is the Latinised name of one of the British deities which by the Roman invaders was adopted and identified with Mars. Several inscriptions to this divinity have been found at other places in the north. The Romans were not indisposed to admit foreign deities to their Pantheon, and another altar found about a mile north of the town is dedicated to the god Jalonus, from whom it is conjectured the river and town take their names.

From the castle the visitors proceeded to St. Mary's Church, the details of which were described by Mr. E. G. Paley. It is a fine specimen of the Perpendicular period, and is remarkable for having a chancel of equal length with the nave. At the east end are stalls of very beautiful workmanship. The Rev. E. F. Letts called attention to the *miserères*, with their curious grotesque carvings, and suggested that the stalls should be restored to their proper position in the choir of the church.

The village of Heysham was visited in the afternoon. The church is chiefly Norman, and has been restored without destroying its original simplicity. On the hill above it are the remains of an ancient Saxon oratory. Close by are the remarkable stone coffins, sepulchres hewn in the solid rock, and well worthy of the critical examination which they received from the antiquaries. In the churchyard there is a stone coffin and a strange "hog-backed" monument covered by rude carvings of the hunting scenes.

A meeting was held in the Amicable Library, Lancaster, in the evening, when there was an exhibition of the local charters, Corporation insignia, &c. Colonel H. Fishwick, vice-president, said that whilst there was no intention of having any lengthy formalities, yet a day so full of instruction and enjoyment, and which he hoped would be the model to be aimed at in the future, could not be brought to a close without thanking those who had enabled them to see so much of a place that was linked with so many memories of the bygone history of the county palatine. The Rev. E. F. Letts proposed a cordial vote of thanks to the local committee. Mr. J. E. Bailey, in seconding the resolution, said he would take that opportunity of making an announcement that would give pleasure to antiquaries all over the kingdom. The Duke of Devonshire had in a very handsome manner undertaken, at the suggestion of the Chetham Society, to bear the cost of the printing and editing of a work of the highest interest and importance to the Lancashire archaeologist, the chartularies of Furness Abbey. The motion having been carried by acclamation, Mr. W. O. Roper responded for the local committee, and in doing so mentioned that he was preparing for publication some extracts from the chartulary of St. Mary's, Lancaster, which was now in the British Museum.

### BUILDING IN BRADFORD.

THAT there is considerable activity, actual and prospective, in the Bradford building trade, says the *Leeds Mercury*, may be inferred from the fact that the masons have succeeded in obtaining an advance of wages, and that the joiners and carpenters are endeavouring to enforce a demand for increased remuneration. For several years there has been almost a cessation of building operations on a large scale, consequent on the depression in the staple trade following upon a period of exceptional activity, during which large blocks of warehouse and shop property were erected, and the needs of the town for some time anticipated. Indeed, so much was this the case, that some three years ago a leading architect expressed the opinion that there was sufficient warehouse property to meet the needs of the town for at least fifty years; and had it not been for the large extent of this class of property from which it has been found necessary to eject tenants to make way for town improvements, this estimate might not have proved wide of the mark. The provision of sites for two new railway stations has also done much towards reducing the plethora of business property in two central portions of the town, a large area of warehouse buildings as well as other premises having been demolished for this purpose. It is not surprising, then, that with the revival of the staple industry there should so soon ensue some improvement in the building trade. The Lancashire and Yorkshire Railway Company are at present in advance of the other companies in the work of providing additional station accommodation. In carrying out the works, various street improvements have been effected; Bridge Street has been considerably widened and the gradient decreased, and Croft Street has been converted into a wide thoroughfare, directly connecting Wakefield Road and Manchester Road. Some old "landmarks" have disappeared in the process—buildings which architecturally may never have been entitled to rank as adornments of the town, but which have had no insignificant place in its moral and material progress. One of these was the Friends' Meeting-house, and another was Zion Baptist Chapel. Wood's Mill, which stood just behind the chapel, and was one of the oldest factories within the borough, had also to be demolished. The delay experienced by travellers in getting into the Exchange Station had been a subject

of complaint for years; this was owing to the circumstance that between 700 and 800 trains daily had to pass through a narrow tunnel, which was locally designated "the Bottle Neck," and which ran under Croft Street and Wakefield Road. In the works now being completed, one of the chief benefits is that a better entrance into the station has been provided by making the permanent way for a distance of 1,250 yards sufficiently wide to admit of another line of rails, and dispensing with the tunnelling under Croft Street. The most prominent feature of the new station is the goods' shed, which is a one-storey building of the usual kind, with cellaring underneath. The shed is 300 feet square, its open glass and timber roof being divided into bays, and supported by iron girders resting on sixty iron pillars. The area of the new yard and shed inclusive exceeds eight acres, reckoning from the new bridge which connects Croft Street with Wakefield Road to the boundary, and three and a half acres are appropriated for shed accommodation. There is yet much to be done before the goods station is completed, but it is already partially in use. When that period is reached, the company will have to undertake the equally important work of constructing a new passenger station, which will occupy the entire site of the present Exchange Station and the Vicar Lane goods premises. It is understood that arrangements will be made for the Great Northern Company's trains to run into the Vicar Lane side, and the Lancashire and Yorkshire Company's trains into the Drake Street side. Extensive additions are at present being made to the goods station of the Great Northern Railway Company in Wakefield Road, which was originally built as a passenger station. The scheme for the Midland Railway Station is of a very extensive character, and the preliminary operations, which are now being pushed forward, have necessitated the absorption of the large block of shop and warehouse property lying between Kirkgate, Cheapside, and the present station. The work of demolition is now being vigorously proceeded with, as also are the other preliminary operations of quarrying and excavating the site.

In anticipation of these operations several large blocks of warehouses were some years since erected on the site of the Union Foundry in Manchester Road, adjacent to the new goods station of the Lancashire and Yorkshire Railway; and recently a successful effort has been made to meet the need for similar accommodation in the vicinity of the premises of the new Midland station by the erection of a large block of buildings at the top of Cheapside, at the junction of Broad Street with Manor Row. The buildings are in seven storeys, the height from the causeway to eaves being 68 feet. The length of the frontage to Manor Row is 150 feet, and to Broad Street 135 feet, the space being sufficient for the storage of about twelve thousand sheets of wool. The buildings are architecturally of the modern English style, without allowing business adaptations to be interfered with. Practically there are seven distinct warehouses in the block, but the whole can readily be adapted for use as one warehouse. The frontage to Manor Row is of ashlar throughout, and three arched doorways give access to the premises at this part, entrances also being provided in the other streets. Mr. Rhodes Calvert, of New Kirkgate, is the architect, and the works have been carried on under his supervision. The building is the property of Messrs. S. Feather and J. Riddihough. In the same thoroughfare, but lower down and on the opposite side, a structure almost equally imposing has been erected for Messrs. Townend, wool brokers, from designs prepared by Messrs. Milnes & France.

In various parts of the town there are building operations of another kind in progress, the most important being at Brownroyd, where Messrs. Isaac Holden & Sons are having their combing works enlarged by the addition of two sheds, the dimensions of each being 320 feet by 180 feet. The area to be covered by the new works is about seven acres. The buildings will be constructed in two storeys, and there will be a chimney sixty yards high for each shed. Sidings connected with the Great Northern Company's depôt at City Road will enable coal and other material to be conveyed direct to the works, and a large part of the yard will be roofed with glass that goods may be unloaded under cover. Generally, the new buildings which are being constructed of stone will correspond with the other portions of Messrs. Holden's establishment. It is expected that in a short time there will be begun some important building operations in connection with the Bradford Infirmary, the need for the enlargement of this institution having been repeatedly pressed upon the Board of Management, and especially during the past two years. It is intended to expend about 12,000*l.* in making this enlargement; and as not more than 2,000*l.* are available towards this, an appeal for funds will shortly be issued to the public. The nature and locality of the addition to the infirmary have formed a subject of frequent and anxious consideration; but, guided by the report of Captain Galton, the Board of Management have decided to make the necessary extension by erecting a detached wing between the eastern end of the present building and Lumb Lane, from designs prepared by Messrs. Milnes & France. It is strikingly indicative of the growing needs of the town that, simultaneously with this addition to the infirmary, the managers of the other principal medical charities find themselves under the necessity of providing more accommodation.

## STRATFORD-ON-AVON CHURCH.

A MEETING of the Stratford-on-Avon Town Council was held on Tuesday when the special report on the restoration of the parish church was discussed. The General Purposes Committee reported that they had received a resolution which had been adopted by the Restoration Committee, after consultation with the Society for the Protection of Ancient Buildings. The committee having fully considered the society's report, resolved to recommend that the fabric of the church be restored in accordance with the principles laid down in the report, and mainly following the recommendations made therein. That if sufficient accommodation can be provided on the floor for seating—say at least 1,050 persons—the side galleries should be removed, the committee recommending that all the seatholders in the galleries should, on application, have allotted to them equivalent accommodation. That the transepts be opened, and devoted to the congregation. In order to utilise the transepts, it will be necessary to remove the organ and to build a vestry. That the committee recommend a vestry be built, detached from the church, but connected with the same by cloisters, on the south side, rather than upon the site of the old charnel-house, as suggested by the Society for the Protection of Ancient Buildings. That an architect be called in to submit a complete scheme to the committee for the repairs and alterations in the church, his instructions being: (1) That the committee approve generally of the principles of the society's report; (2) that they require advice, with sufficiently-extended details and rough estimates, as to what he would propose should be done under the following heads; (3) repairs to the fabric; (4) the seating, galleries, &c.; (5) removal of the organ; (6) the vestry; (7) other work required or suggested. The committee guarantee that a fee, not exceeding fifty guineas, shall be given for such report, but in no way pledge themselves to adopt any of the suggestions to be made, or necessarily to employ the same architect to carry out the work they may decide to undertake. The Restoration Committee have selected Messrs. Bodley & Garner to furnish a detailed scheme, with estimates of the probable cost. The following resolution was adopted, "That the report of the General Purposes Committee be received, and the action of the members appointed to serve on the Restoration Committee be approved; but the Council, while generally approving of the scheme of restoration proposed, reserve their final decision until they are in possession of a fuller report, with details and estimates, to be furnished by the architects appointed by the Restoration Committee, viz., Messrs. Bodley & Garner."

## PROSECUTIONS BY DISTRICT SURVEYORS.

IN the House of Commons, in May last, Mr. Samuelson put a question, at the request of the Mansion House Council on the Dwellings of the Poor, to the Chairman of the Metropolitan Board of Works, whether, when the district surveyors under the Board took proceedings for infractions of the Building Acts, they did so at their own risk; whether the responsibility as to costs rested on them, so that if unsuccessful in the prosecution instituted, they were personally liable for the costs; and whether the Board would take steps to prevent the surveyors being thus deterred from seeing that the Acts were complied with. Sir J. M'Garel-Hogg replied that though the surveyors were appointed by the Board of Works to enforce the Building Acts, they had statutory authority to take proceedings in their own names and authority, and thus incurred the same risk as other suitors in regard to costs if unsuccessful in prosecution. On the other hand, the surveyors were entitled to considerable fees when successful in obtaining convictions, though they had to sue in the ordinary way for payment if the defendants were unable or unwilling to pay. Sir J. M'Garel-Hogg added that in cases in regard to which points of law had been reserved for consideration by a higher Court, the Board had been accustomed to pay the surveyors' costs. Mr. John Hamer, the hon. secretary of the Mansion House Council, has officially called the attention of the Home Secretary to this inquiry by Mr. Samuelson, and to the answer of Sir J. M'Garel-Hogg, observing that the Council would be glad to learn his opinion on the question, and whether he would "use his influence to procure such alteration in the law as to make the public authority responsible for prosecutions instituted by district surveyors." To this Sir William Harcourt has replied as follows:—"Whitehall, June 25.—Sir,—With reference to your letter of the 11th inst., 1884, asking for an alteration in the law so as to make the public authority responsible for prosecutions instituted by district surveyors appointed by the Metropolitan Board of Works, for the purpose of enforcing the regulations of the Building Acts, I am directed by the Secretary of State to inform you that the Building Acts will be under the authority of the Corporation of London, as proposed in the London Government Bill, who will, no doubt, take the measures they think necessary to make these Acts more efficient.—I am, Sir, your obedient servant (signed), GODFREY LUSHINGTON."

## NOTES AND COMMENTS.

THE Art-Director at South Kensington, in his notes on Italian Art Schools, suggests that the English schools should obtain casts of hands and feet from shapely models. If he wished to cite a case in support of the proposed innovation, he need only refer to the cover of the official programme of the Health Exhibition. It is adorned with a pleasing figure of the goddess HYGEIA, by one of the successful South Kensington students. But there are no less than seven toes on the right foot. One of the Royal Academicians has a cabinet, on which there is painted a figure of a harpist with six fingers on one hand, and the addition seems to impart so much energy that he would not allow the error to be rectified. But can a seven-toed foot be supposed to be more efficacious in stamping out disease than one with the ordinary number? The absurdity is easily explained. The South Kensington School continues to feel the influence of the late GODFREY SYKES, who believed that one of the surest ways of expressing energy was to make hands and feet of abnormal dimensions. The practice might be abated somewhat if the London and provincial schools possessed casts of good hands, and of feet which had not been distorted by boots.

AN exhibition of drawings by the pupils of the Board schools of London is now open in the basement of the school in Saffron Hill. It is interesting as denoting what progress is made in ordinary schools. What first strikes the visitor is the absence of system in the teaching. In too many of the schools the pupils are allowed to copy woodcuts, illuminated sheets, and hideous chromo-lithographs, and the more dexterous they become in imitation of the originals the less chance they have of acquiring skill in drawing. Other schools patronise examples which have been engraved in fine lines, and which it is almost impossible for a novice to imitate. The majority of drawings bear the signs of having been rubbed out very often, as if there was no necessity to inculcate decision. The drawings which have been taken from solid models are very few, and in too many cases it is evident that the showiness which is likely to deceive ignorant parents has been preferred to the true interests of the children. The London School Board, in their room at South Kensington, display engravings from figures by RAPHAEL and other masters, as if they were the kind of studies which are followed in schools; but in the Saffron Hill exhibition we see no copies from them. Probably they are only intended to excite the admiration of foreign visitors and jurymen.

THE School Boards of London, Birmingham, Edinburgh, and Glasgow have gone to much expense in order to exhibit their educational appliances at South Kensington. But a visit to the room upstairs which has been assigned to the Christian Brothers will make it plain to every taxpayer that the English authorities have much to learn. The Romanist teachers are far in advance of us. Their notion is that a school course is a preparation for the workshop, and they act upon it. They may be in error, but they at least gain consistency in their teaching. Looking at the examples of work from Board schools, it is impossible to say whether the Boards and their teachers ever bestow a thought on a boy's future. The Acts say nothing about the future, and, so long as the law is obeyed, what need have members and masters to give themselves trouble for which there is no recognition? Boys may come and boys may go, but the Board remains. The Christian Brothers are not so bounded in their views. They first do all that they can to prepare boys for apprenticeships, or for business, by making them acquainted with real things and processes; afterwards they assist them, as the lads grow, with advice and instruction. Thus, for example, several note-books are to be seen which are full of sketches of machines, and have been taken in the workshops. If a youth has the wish he is taught how to make the sketches, and afterwards to prepare elaborate drawings from them. It is so in other trades, and a glance round the room shows that there are chemists, builders, carvers, geologists, engravers, printers, &c., enrolled among the Brothers. Some of the work done by pupils appears to be too good for boys' hands. The demand of the age being for technical education, the Brothers have in their own way elaborated a system of training, which apparently is more complete than those which have been devised by the Governments of Europe, and their exhibits at South Kensington are worthy the attention of everyone concerned in education.

THE French architects, at their late congress, heard with applause of a project for creating a fund which will be available for the defence of the interests of architects. The entrance fee is proposed to be thirty francs, and the annual subscription twelve francs. It often happens in France as in England that an architect suffers from clients and public bodies because he is unable or is afraid to undertake the risk of law expenses. In England there is the additional annoyance to him that his Institute will take no recognition of his difficulties, however grievous they may be; but the French society is not likely to allow a member's rights to be sacrificed to the timidity of a few under the guise of dignity and the "interests of the profession in general." The funds of the proposed society will not be available unless the council can find, after investigation, that the case is one which demands their interference, and it is possible that the society may often be enabled to keep cases out of the Courts. The members will have the satisfaction of feeling that in a difficulty they will be sustained by the influence of the society, which can be exercised in other ways besides advancing money for law costs.

THE sale of the pictures from the Leigh Court Gallery corresponded with the predictions. The National Gallery acquired the two pictures by HOGARTH—which, like so many of the painter's works, preserve their freshness—and STOTHARD'S *Canterbury Pilgrims*, which is hardly equal to the reputation it has gained through the excellent engraving. The faces show uncertainty of touch, as if the painter's eyesight had been failing before this replica was undertaken. TITIAN'S *Venus and Adonis* could not find a bidder who was willing to speculate more than 1680 guineas on its genuineness, and was bought in. The *Three Graces*, which, although ascribed to TITIAN, were unlike any other work of his, were sold for 220*l.* 10*s.*, which was rather a high price for such a painting. A small head on copper—*Mater Dolorosa*—which apparently is one among many replicas after CARLO DOLCI, sold for 383*l.* 5*s.* A noble picture by MATTEO CERREZO, but which may hereafter be traced to a greater artist, realised 682*l.* 10*s.* The little panel by RAPHAEL was bought by MESSRS. AGNEW for 588*l.* The same purchasers secured the three principal works by CLAUDE LORRAINE, paying 6,090*l.* for the two companion pictures, *The Landing of Æneas* and the *Sacrifice to Apollo*, and 3,990*l.* for the *Landing of Æneas in Italy*. The conclusions to be drawn from the sale are that buyers are willing to give good prices for ancient works by great masters—when their authenticity is undoubted—but that it is now more difficult than ever to prove that title.

It is not often that there is a chance for buying an entire island. On the 29th inst. MESSRS. DEBENHAM, TEWSON & Co. will offer for sale in London the island of Herm, which is situate between Guernsey and Sark. It measures a mile and a half in length, and is about three-quarters of a mile in width. The present population is only about thirty-seven. Upon the island are an hotel, several residences, a school-house, harbour, and granite quarries. With an island of this area it would be possible for a philosopher to try all sorts of experiments in public economy, but it is more probable that it will be purchased as a holiday resort, and it would be difficult to find another which has such peculiar advantages.

THE Theatre Royal, Edinburgh, has once again succumbed to fire. On Monday, during the rehearsal of "The Nightingale," flames were found to issue from a room in which properties belonging to the last Christmas pantomime had been stored, and in the course of a couple of hours the building was destroyed. It was found that even the brick wall between the stage and the auditorium was unable to resist the heat. English visitors to Edinburgh will remember the position of the house. It stood at the corner of Broughton Street, and faced the broad road known as Leith Walk. The position was not unfavourable for the firemen's exertions. Theatres are allowed to be erected in unexpected places in towns, but the Edinburgh Theatre adjoined a pro-cathedral. On a former occasion when the theatre was burning, the Dean of Guild and several firemen were killed in endeavouring to save the church. There is apparently some fatality about the site, and the civic authorities should insist on the new building being as nearly fireproof as it can be made.

BANQUETING HALL, HALLYBURTON HOUSE, FORFARSHIRE.

HARMONY WELCOMING THE NATIONS.

ALTHOUGH poets have so often sung in clarion tones about war and warriors, they have also had visions of the reign of the meek-eyed Peace, and in a variety of forms, from epics to lyrics, have expressed the simple prayer which was heard in the Catacombs, "Dona nobis pacem." HOMER saw the vision amidst scenes of broil and battle; it inspired VIRGIL, and so effectually that, in spite of the poet's dying wish that the poem should be destroyed, the "Æneid" was utilised by AUGUSTUS as if it were a State paper written to support his policy. DANTE forgot his revenge for a while in thinking of what Peace was to do for Italy; MILTON believed that in the beginning of our era she had reigned on sea as well as on land, and was to rule again:—

No war, or battle's sound,  
Was heard the world around;  
The idle spear and shield were high up hung;  
The hooked chariot stood  
Unstain'd with hostile blood;  
The trumpet spake not to the armed throng.

When a new pleasure was created in our time by international exhibitions, the poets once more sang of Peace. THACKERAY, who was not disposed to think over-much of human perfectibility, fancied for a moment, with a thrill of love and awe, that even Vanity Fair might know something of the anticipated millennium. Mr. TENNYSON, to whom, in the interval between exhibitions, Peace was no more than a commonplace shepherdess piping on her pastoral hillock a languid note when she was not thinking of what sheep were to fetch in the market, in his turn had the old dream and saw men

Breaking their mailed fleets and armed towers,  
And ruling by obeying Nature's powers,  
And gathering all the fruits of Peace,  
And crown'd with all her flowers.

Whether there is any sincerity in a poet's preference of peace to war it would be difficult to discover. It is his endeavour to express thoughts which will gain approval, and he claims a good deal of latitude in consequence. As the shrewd Frenchman said, "Si les Titans avaient chassé JUPITER, les poètes eussent chanté les Titans," and they would have gained applause from others besides the victors. It is not therefore surprising that, when M. LAMEIRE prepared his colossal piece of decorative painting for the Salle des Fêtes of the last International Exhibition at Paris, he was inspired, like one of the poets, by the sentiment which then prevailed, and that he desired to make the world know that the Republic, unlike the Empire, was synonymous with peace. In this case the presiding spirit is France itself under the type of Harmony, and all the nations are under the influence of her spell. The northern nations, Denmark, Sweden, and Norway, bring with them the banner of COLMAR, and are guarded by the wolf of ODIN. Next stands Holland, who seems to have been suddenly attracted from her dairy farm, and to have snatched an oar on her way. England is an Imperial dame, at whose feet the Indian elephant kneels, and no less dignified are the figures of Austria, Hungary, and Belgium. Italy, as becomes her position in any assembly relating to music, stands crowned with laurels. Near her are Spain and Germany. The two turbaned Turks are portraits of architects who are among the artist's friends. On the opposite side are the figures which are emblematic of Greece and Russia, North and South America, the Pacific Islands, and the East, while at the ends we see the envoys of Japan and Egypt hastening with all speed to Paris. The difficulty of arranging figures to fill a space of the form that is indicated in the illustration will be apparent at a glance, and the poetry and invention of M. LAMEIRE are evident if his design is compared with any of the processions of workmen of different nations which commonly constitute the tributes from the painter's art to international exhibitions. M. LAMEIRE always avoids stereotyped plans, and whatever may be the subject he undertakes we are sure to have something original from his pencil. It might be said that his works are characterised by a combination of learning and inspiration, and that one quality enhances the other. M. LAMEIRE has studied the decoration of all ages without becoming a pedant, and his mind is so well balanced that his invention can be allowed full play without any fear that it will produce freaks

or frivolities. There would be no risk in entrusting to his hands a Gothic cathedral or a boudoir; he has decorated churches in all styles, ancient and modern châteaux, public buildings and private houses. His work is to be seen in Amiens and Périgueux as well as in Paris, London, and Rome, and he is alike competent to design a brooch or to aid in the deliberations of the Commission des Monuments Historiques. It was by the archaeological accuracy as much as by the originality of M. LAMEIRE'S designs that the late WILLIAM BURGESS was impressed, when he proposed that the drawings for the "Catholicon" should be purchased by the Science and Art Department, and sent about the country to the various art schools, in order that they might be studied and copied. For that design M. LAMEIRE obtained the first medal for architecture and the Cross of the Legion of Honour at the Universal Exhibition of 1867. But it must be said that he has always co-operated with architects instead of superseding them. The original tympanum measures 140 feet in length, and the figures are about 18 feet in height.

BANQUETING-HALL, HALLYBURTON HOUSE, FORFARSHIRE.

THE banqueting-hall, which is on the principal floor, forms the *motif* of the plan of this house. Placed close to the entrance-hall and staircase, and giving access to drawing-room, billiard-room, and family suite, it fills exactly the position of the hall in old English manors. The walls are wainscotted to a height of 13½ feet, and the ceiling is arched in oak, having moulded transverse and diagonal ribs and carved bosses at the intersections. The hall is lighted from the south-west by a large traceried window of five lights. A recessed fireplace, forming an angle-nook with side seats, is placed at the north-east end, and is divided from the hall by arcading in oak, which supports a minstrels' gallery richly groined on under-side, which is reached from the main staircase. Passages to bedrooms running along both sides are lighted from the hall by means of arched openings filled in with balconettes, and are connected with the gallery. A large recess on the west side beneath the gallery, with polished and moulded stone archway and large three-light window, forms the bower, and gives light to this end of the hall. The dimensions of the hall are—length, 60 feet; width, 22 feet; height, 27 feet.

The joiner-work has been admirably executed by Mr. SHILLINGLAW, Edinburgh. The architect is Mr. ANDREW HEITON, F.R.I.B.A., of Perth.

## AN ARCHITECT'S DIFFICULTIES.

A MEETING of the Carlisle Board of Guardians was held on June 26, when Mr. Oliver, the architect of the hospital at the workhouse, attended the meeting, and the clerk read the following communication from him bearing upon the question of the delay which had taken place in the erection of the hospital:—

"I have received a copy of the resolution passed at the last Board meeting together with a copy of the report of the Hospital Building Committee. Referring to the latter, I beg to say that I agree generally in condemning the delay in the progress of the buildings. I feel I shall have no difficulty in showing that I have done all in my power to hasten the completion of the works, and for that purpose I must draw the attention of the Guardians to the real causes of the delay. I consider them to be fourfold:—1st, altering the position of laundry block; 2nd, slating; 3rd, heating, hot water, and steam supply; and 4th, general dilatory behaviour of contractors.

"1st. With regard to the altered position of laundry block. On September 15 last, according to instructions, I stopped the builder from proceeding with laundry buildings in the position first intended, and it was the second week in November before he was authorised to proceed with their erection; thus fully two months were lost in starting these buildings, at which the contractor complained.

"2nd. Slating.—I wrote to the slater on September 22, and again on September 27, complaining of the delay. On October 22 I wrote complaining again, and threatened to lay the matter before the Building Committee; on October 31, and again on November 2, I urged more progress (about this time I took a large contract out of his hands which had been accepted, and placed it in the hands of another firm at Penrith); on November 20 I wrote again, and afterwards reported the delay to the Committee; and on November 28 I gave him seven days' notice to complete his contract, failing which I threatened to employ some other contractor, charging him with all expenses. The work then proceeded rather better, but on February 19 of the

present year, some part of the work in the main building being still incomplete, I wrote informing him that I should advise the infliction of the penalty named in the contract. I wrote again on February 23 and on March 25. I ordered him and his men off the works, and advertised for slaters. I had no reply to the advertisements, as the effect of the severe storms at that time was keeping slaters fully employed. In addition I have frequently seen the contractor for the slating, and urged on the progress, and so has the clerk of works.

"3rd. Heating, hot water, and steam supply.—On October 2 tenders were invited for the engineering works, and it was not until November 17 that I had instructions to accept Messrs. Haden's tender. Of course, after the acceptance of their tender a great deal of material had to be specially prepared, and a much more elaborate system having been adopted than first intended, structural alterations and additions had to be made to suit. I need not point out that the mere fact of the heating pipes and hot water supply not being fixed prevented the progress of other works.

"4th. As I have already stated, notwithstanding the principal drawbacks to which I have referred, I have on numerous occasions urged the contractors to expedite the works, and as recently as Whit-week I found fault with Haden's for taking their men away (it being a general holiday in Manchester) at a critical time, and causing delay to other trades.

"I must now refer more particularly to the report of the Hospital Committee. It states that from the day of my report on April 16 to June 10 the laundry block is almost in the same state as it was eight weeks ago. In my report of April 16 I stated that very little progress could be made with the laundry block until the acceptance of tenders for the drying-closet fittings, &c., and it was not until May 17 that I was authorised to accept Messrs. Haden's estimate. The committee report is dated June 10. The reason of delay is obvious. I am glad to be able to report that satisfactory progress is now being made with every part of the works. The main buildings are now nearly completed, and the painter is at work. The annexes to old buildings will be completed this week. I am afraid that some time will be lost next week owing to the races. I fully expect the works will be entirely completed in about five or six weeks, and the Board may rely on my using every effort to insure this being done."

## THE GREAT EXHIBITION OF NEW ORLEANS.

THE buildings for this gigantic exhibition are now being rapidly pushed forward. The exhibition promises to surpass in size that of the London Great Exhibition of 1862, as well as the recent Centennial Exhibition, in the number of its exhibits. The London buildings of 1862, which up to that time was the largest exposition structure ever erected, contained 1,400,000 square feet. But the main building at New Orleans will contain 1,656,000 square feet, requiring 9,000,000 feet of lumber, 4,500 kegs of nails, and 5,000 boxes of glass, in its construction. It will be 60 feet high, with a tower 115 feet, and it will have a music-hall in the centre with a seating capacity of 11,000. To light the building there will be 15,000 incandescent lamps, and the steam required for the whole structure will be upwards of 3,000 horse-power. The horticultural hall is a handsome structure, 600 feet long by 194 feet wide, with glass roof and glass tower 90 feet high. This will form the largest conservatory in the world. It is intended to arrange around the sides specimens of the choicest plants from Mexico, Central America, Florida, California, and all parts of the United States and Canada, and a special commissioner will visit Europe for the purpose of securing specimens of fruits and plants in order to make this display international in character. The centre of the hall will be devoted to an international fruit display, presenting 20,000 varieties. This is nearly double the quantity of any previous fruit exhibit. There will also be an art gallery. About 1,000 men are engaged on the work of the main buildings, which will be ready for the reception of exhibits in August next.

## THE HELLENIC SOCIETY.

THE annual meeting of the Hellenic Society was held at 22 Albemarle Street on June 26, when the chair was taken by the Bishop of Durham, the president of the society. After the adoption of the Council's report, which gave an encouraging account of the progress of the society, the president delivered an address upon the work that had been done hitherto, and that might be done in the future. After expressing regret that he was only now for the first time appearing in the office which he felt it a high honour to hold, the Bishop of Durham sincerely congratulated the society upon its achievements so far. The journal, for its originality and scholarship, for the interest and variety of its articles, might challenge comparison with any similar periodical, whether English or foreign. Referring to the forthcoming reproduction by photography of the Laurentian Codex of Sophocles, the president said that the reproduction of any unique manuscript was

of essential importance, in the case of its loss by fire. It was satisfactory to note that the society had taken an active part in promoting the scheme for a British school at Athens. It was hardly creditable that England should be so far behind her neighbours in the establishment of such a school, considering her close political connection with Greece, and her really wide interest in Greek literature. Until there was such a centre of work established on Greek soil Hellenic studies in England would be at a decided disadvantage. Referring to the society's work in the field of exploration, the Bishop of Durham said that, perhaps, to most scholars Hellas proper presented greater attractions, but for his own part he ventured to think that the ground which had actually fallen to the lot of the society would yield even richer results. Beneath the soil of Asia Minor lay hidden the key to many an interesting problem in history and ethnology. As an example might be cited the light recently thrown upon the remarkable extension of the Hittite empire. Referring to his own special line of study, the president dwelt in some detail upon the value of Mr. Ramsay's discoveries as illustrating the early history of the Christian Church in Phrygia, and showed by several examples how much might be learnt even from the finding on an inscription of a single name. Mr. Ramsay had still before him important and numerous discoveries, and it was greatly to be hoped that his work would not be hindered by lack of funds. The president, in conclusion, threw out two suggestions for the society's work in the future. In the first place might be undertaken by competent persons the thorough investigation of the monastic and other libraries in the East. The investigators should be competent in every branch of Hellenic study, or some manuscripts of great value might escape if they chanced not to belong to their special department. Thus the invaluable manuscript of the Epistle of Clement of Rome was found only a few years ago in a library at Constantinople which had been already examined by three trained scholars, English, French, and German, all of whom were no doubt concentrating their attention on the discovery of classical manuscripts. But from any point of view the discovery of a piece of genuine Christian literature of the first century A.D.—that great crisis in the world's history—was surely of the highest importance. Another work that might usefully be undertaken by the society was the mapping out of subjects to be worked upon by competent young scholars, who would devote time and labour to their solution. Many vexed questions might be cleared up in this way. While congratulating the society upon its achievements in the past, the president trusted that its ambition would not stop there, but push on its conquests to regions yet unconquered.

Mr. Gardner stated that the next number of the "Journal of Hellenic Studies" would not be published until the autumn, by which time an ample supply of papers would be forthcoming. He thought that if the excellent advice of the president as to the mapping out of subjects for investigation could be followed at Oxford and Cambridge the greatest benefit would result both to the individual workers and to the cause of learning at large. Mr. Newton, in moving a vote of thanks to the auditors, took occasion to refer both to the work of the society and to the general progress of archaeological research during the past year. He was peculiarly glad to hear from so great an authority as the president of the society so high an estimation of Mr. Ramsay's work, for he had himself been concerned in appointing Mr. Ramsay as a travelling Fellow to the University of Oxford and in indicating his field of labour. Under extraordinary difficulties and in a comparatively short time Mr. Ramsay had established important historical results. Alluding to Mr. Wood's discoveries at Ephesus, Mr. Newton said that the inscriptions published in his book gave no idea of the store of facts contained in the mass of Ephesian inscriptions at the British Museum. In these, which had been carefully examined by Mr. Hicks and would be published next year, a new and most instructive light was thrown upon the constitution of the great hierarchy which governed the Temple of Artemis. It was a shameful thing, said the speaker, that when the Government grant had been exhausted Mr. Wood's frequent appeals to the British public for funds to carry on his researches had been practically unheard; whereas, when the grant made by the German Government for the excavation of Olympia had been exhausted, a sufficient sum was at once raised by private subscription to complete the excavation of the Altis. The great hope was that young men were now being trained at our Universities who would be in time competent to carry out the work of exploration. For twenty years past, in France and Germany, there had been a constant succession of young scholars, first sent to the schools at Athens, then upon special missions, and in course of time promoted to chairs of archaeology at the different Universities. Such a supply of men, and such means of steady promotion, we might one day hope to see in England. After pointing out that much help might be given to exploration by wealthy Englishmen who went year after year to the Mediterranean in their yachts, Mr. Newton concluded with a rapid survey of the discoveries of the year, dwelling especially upon the remarkable tomb of a Seleucid monarch found by the Germans in Kurdistan. In Greece the plan of the temple at Eleusis had been finally established, and at the entrance of the Temple of Æsculapius at Epidaurus had been found a set of inscriptions recording in detail how certain miracles were worked.

## GRAND AVENUE MANSIONS, WEST BRIGHTON.

THE new mansions which have been for some time in course of erection at West Brighton by Mr. John T. Chappell, of Lupus Street, Pimlico, have excited a great amount of interest among the inhabitants and visitors. They are an experiment in construction and arrangement and a testimony of the owner's enterprise. The elevations have been designed by Mr. G. Sherrin. The principal fronts are faced with white pressed gault bricks, with moulded window reveals and stone heads, ornamental brick and stone strings, cornices and parapets, with terra-cotta balusters, Portland stone balcony landings, supported by carved stone trusses to the first-floor reception rooms of Grand Avenue Mansions and Airlie House; the forecourts, piers, and dwarf walls in pressed gault bricks, Portland stone plinths, copings, and pier caps, with terra-cotta balusters; Portland stone steps, with Mosaic pavings to entrance. The open areas are paved with asphalt. The reception-rooms on the south front overlook the private lawns and the sea, of which there is an uninterrupted view. The bedrooms of the eastern residences look on the Grand Avenue, whilst those of the western residences face the west. The domestic offices in each case face the north. Albert Mews, which comprises seven sets of stables, is approached from the Third Avenue by a private road, which also gives access to the tradesmen's entrance to Grand Avenue Mansions and Albert Buildings. Airlie House, which separates the north and south blocks, will be let as a private residence, and Grand Avenue Mansions and Albert Buildings are arranged for high-class residential flats. There are very commodious business premises on the ground floor of Albert Buildings. The Grand Avenue Mansions have two residences on the ground floor (which is about 5 feet above the pavement) and the same on each of the four floors above, ten in all, with porters' rooms, and the extra rooms on the lower ground floor, any of which can be let to the tenants of the residences if required. The principal entrance, main stairs, and hydraulic passenger lift are on the south front, where a porter will be in attendance. There is a secondary staircase with luggage lift approached from the north front, with access from the private road leading to Third Avenue. The staircases are of stone, and the principal stairs are carpeted. The landings are of Mosaic, and the walls and ceilings decorated. The floors and roof of the building are of fire-proof construction. The western residences have at the south-west corner and approached from the dining-room an extra room large enough for a full-size billiard table, with lavatory, or the room could be used as a bedroom, or could be divided into bed and dressing-room, with lobby entrance, slop sink, and broom closet. In addition to the library, dining-room, drawing-room, and five bedrooms, each residence has a kitchen fitted with range, scullery, with stoneware glazed sink (hot and cold water), fitted table, draining-boards; a china closet, with lead-lined sink (hot and cold water), and fitted cupboards; a bathroom with copper enamelled bath (hot, cold, and sea water), three w.c.'s, one being fitted with lavatory (hot and cold water), larder, wine cellar, coal cellar (in addition to the one in the vaults), and ample and complete stores, an ornamental fitting in bedroom corridor, containing four cupboards, several drawers, table top, and fixed mirror over. The sanitary arrangements are carried out on the most approved principles with the best appliances; the soil pipes are in all cases outside the residences, and are ventilated, as are also the drains. No pipes of any kind enter the dwellings except those actually belonging thereto. Each residence is appropriately decorated; all the reception-rooms have hard wood chimney-pieces, with marble joints, marble fenders, and tile hearths; the best bedrooms are similarly fitted, but the wood chimney-pieces are painted and decorated to correspond with the woodwork of the rooms. The floors of the reception-rooms, corridors, and best bedrooms are of pitch pine, prepared for polishing. Stained glass of appropriate designs is introduced in lobby and corridor windows and in all lobby screens and dining-room doors. Venetian blinds are provided to all the principal windows. Gas services and electric bells are fitted throughout, and the walls and ceilings of every part have been thoroughly dried by Ligny's patented process. All the rooms and principal bedrooms are large and well-lighted, and those on the third and fourth floors slightly exceed those below.

On Saturday last Mr. J. T. Chappell conducted a party of visitors over the Grand Avenue Mansions, and then explained the arrangements. He said that he had for some years made the construction of residential flats a subject of special study, and felt that this class of building was now coming into much greater favour than formerly. Such buildings were especially valuable in towns like Brighton and Hove, where there was but a limited amount of sea-frontage, and that eagerly sought for, as they enabled a much larger number of persons to enjoy a residence on the front of the town than could possibly be provided with private houses of the ordinary kind. Proceeding, he said he had carefully considered the objections and difficulties in connection with flats, and having examined the plans of nearly all the flats in London, had been able to reduce to a minimum, if not to entirely abolish, all the objections which could be raised against this kind of residence. He explained that each residence in the mansions was

entirely separated from the others, even from the neighbouring set of apartments on the same floor, and that the sanitary arrangements had been so arranged that one tenant could not be annoyed by defects arising in consequence of carelessness or otherwise on his neighbour's premises. All pipes were carried in bricked cases outside the building, and in these cases ladders were permanently fixed so that a workman could ascend to either floor, take off the caps, which were fitted at each connection, and clean out pipes running into the flats without entering the residences at all. All the chimneys were lined with circular terra-cotta tubes, in order to prevent a large accumulation of soot, and each one had been tested and found perfect. He also explained the perfect ventilation of the drains and pipes, and the chemical test to which the work had been put to prove its stability, and then referred to the perfect water supply, which is laid on the most approved principle, all water except for the water-closets being drawn direct from the mains. He gave details as to the construction of the fire-proof floors, and the means of ventilation employed, and concluded by giving an outline of the general construction, which has been fully stated above.

## TECHNICAL EDUCATION ON THE CONTINENT.

AN address was delivered by Professor Roscoe, of Manchester at the close of the first year's courses of the Dundee University College on June 26. After distributing the prizes, the Professor said:—If we look back to the beginning of the century, we find that the Germans had established about a score of Universities in that series of different kingdoms which has now been joined together to form the great German Empire. At present there are twenty-four such Universities, with no fewer than 35,000 students undergoing tuition of different kinds in the various faculties of these twenty-four German Universities. At the beginning of this century these Universities existed, and had existed for many generations; but, whilst England was progressing and making large strides in industry and commerce, in Germany such an industrial system was unknown, and the large factories of England gained complete possession of the trade of the world. We in England knew how to spin cotton and flax, and how to make locomotives, and how to build railways, and that knowledge was gained by us alone, and the consequence was that at the end of the great wars the Germans found themselves face to face with a complete industrial system in this country, which was altogether unknown in theirs. The Germans, therefore, began to ask themselves in what way they could endeavour to obtain a portion of these great manufacturing industries; how they could employ their people as we were employing ours, and they said, and that very truly, that in order to educate the class of men capable of carrying on such practical work the existing schools and Universities were insufficient. The schools did not give instruction in such subjects as those of engineering, chemistry (theological and applied), and physics (pure and applied). Hence the German Governments started what have since been called polytechnic schools, and now there are no fewer than a dozen or more of these large polytechnic schools situated in different centres of Germany, in which the subjects taught are to a great extent the same as those taught in the University, but to these others have been added the practical sciences, such as engineering, which were not and are not in the curriculum of the Universities. Now, the number of these polytechnic schools which have been established and the expense to which the German Government have gone, not only in building, but in supporting their schools, is something very large indeed—something we have no idea of in our country. Then you must remember all the work done in the way of education is done by the Government. In these countries as yet, ladies like Miss Baxter or gentlemen like Charles Beyer, of Manchester, and others whose names are on the honourable roll of donors of great sums for educational purposes do not exist, or the Germans have not as yet gone so far as us in that wise and beneficent way of spending their money. They rely on the Government. In that country the Government supplies all the money, and fees are placed at a very low figure so that all or almost all students desiring to obtain knowledge of the kind may get the information and education they require. To mention only one of these: I dare say many of you have seen that beautiful building situated in the town of Zurich, the large polytechnic school of that town, which has been founded by the Swiss Federation. They built the school, they pay the professors, and the students come not only from all parts of Switzerland, but from all parts of the civilised world to benefit from the instruction there given. We have seen the work that your Professors do here—the small number of them you see before you. If I had been engaged in a similar ceremony at Zurich I should have had forty-five professors behind me and thirteen assistants. The number of courses in the Zurich school is no less than two hundred. The cost of this school is extremely great. For example, they have just found their chemical laboratory insufficient for its purpose, and the Government of this little Federation have just voted 50,000*l.* for building a new chemical laboratory for the Zurich Polytechnic. Nor is this

money voted without a view to economy. In their Chamber the other day this subject came up, and the question was raised as to the economical value of such an expenditure on a laboratory, when it was stated, in answer to the objectors, that this sum was small compared with the amount of money earned by Switzerland by the establishment of works in which chemical knowledge was necessary. It was pointed out that the men who were erecting these great works—colour works, dye works, and calico printing works—had all been educated in the polytechnics, and that without this education these industries would be carried off to other countries, so that it was really a question of economy to vote this 50,000*l.* for the laboratory at Zurich. Then at Hanover a large polytechnic school has been established. The kingdom of Hanover has ceased to exist, and the Welfenschloss built, I believe, by the late king has been turned into a polytechnic school, at a cost of 350,000*l.*, while the cost of the collections of minerals, apparatus of one kind or another, and a museum necessary for the illustration of the subjects taught has been 26,000*l.*, and the expenditure for the maintenance of these collections about 1,200*l.* per annum. Again, if we go to Berlin, those of you who have visited that city know that in the neighbourhood there is a castle where the German Emperor sometimes resides. An enormous building has lately been erected there—not a palace, but a polytechnic school—at a vast expenditure of money, a good deal of which, I believe, came from France. The actual sum spent has been about 650,000*l.* I mention these facts to show you the interest taken in Germany in this great subject of scientific education, and to tell you what they think it is necessary to do; for as a German said to us:—"You Englishmen are a practical people, and you very well understand that we in Germany, highly taxed as we are for our military system and other necessary evils, would not vote large sums of money to be spent on educational purposes unless we believed it paid us to do so." The fact is that the establishment of these polytechnic schools has without doubt had an enormous influence upon the industries of Germany. We hear a great deal about foreign competition—about the manufactures of Crefeld and Chemnitz being sent into neutral markets against our own. The German opinion is that that position which they have gained has to a great extent been due to their determination to educate themselves at all costs, and to bring themselves up to the point which is necessary in order to carry on these great industries successfully. There are now almost no locomotives of English manufacture to be found on the Continent. On some of the lines which are worked by England, as for instance the Dutch-Rhenish, the Manchester locomotives are seen, but on all the other lines English locomotives have been discarded. They build their own engines, and their mechanical work is as good and as perfect as anything we can do in this country. Well, then, the origin of these polytechnic schools I have endeavoured to point out, and also their works; but it is only proper to say that this thing may be overdone, and at the present moment this seems to be the case in Germany. For, now that Germany is united, the number of these polytechnic schools is really greater than is needed, and we find on examination that, whilst the number of scholars who can be accommodated in these great schools amounts to 6,000, there are at the present moment not more than one-third of that number being educated. The fact is that the great demand which arose twenty years ago for building railways and carrying on engineering works of all kinds has to a great extent ceased, and the consequence is that the number of young men who attend these special engineering schools in Germany is now very much less than before; thus we found large rooms in large buildings devoted to the subjects of drawing and practical engineering very sparsely inhabited. This, then, is clear, that the Germans have run rather too quickly, and that they have done more than was absolutely necessary for the purpose; and yet there can be no doubt that these schools have exerted the very greatest influence on the commercial and manufacturing sections of trade, and that without these schools Germany never could have accomplished what she has accomplished. While such has been the case, the question may naturally suggest itself to those who look at this system from an outside point of view, Why not teach in the present Universities the practical subjects which are necessary? Well, that was the question which the Germans themselves have solved in one way. They say—We like to continue our University education on the old lines, and we have many reasons for thinking it desirable not to bring the practical subjects into the University curriculum, but rather to have separate schools for that purpose. But almost all scientific men and men whose business it is to weigh questions such as I am now considering, tell us if they had to do the thing again they should do it differently, and it would be the greatest mistake for us in England and Scotland to start separate institutions of this kind—one for teaching the practical sciences, and the other for teaching literature and the old literary learning. It is very gratifying to find that the lines which you have drawn out for yourselves here in Dundee and those drawn out by us in Manchester, in Liverpool, by the authorities in Cardiff, by the people in Bangor, in Leeds, in Sheffield, and in other large centres, are exactly those which, from our knowledge of what has been done in Germany, we think the best—that is to say, not to sever your subjects, but to make a University College, as your name implies,

an institution in which not only the subjects which are necessary for the advancement of our great industries—chemistry, whether pure or applied; mathematics, which is the foundation of all sciences; physics, again, whether pure or applied as in your classes of electrical engineering—that classes of that kind should be joined with others of a less practical but no less necessary character, viz., the old lines of literature and of language which have formed the basis of man's education since time was.

### UNDERPINNING WALLS.

A DECISION has been given in an action which was brought by Messrs. Hastie & Co., of Greenock, against the Police Board. The plaintiffs are the owners of a dwelling-house at the junction of Kilblain Street with Nicholson Street in Greenock, the entrance to which was formerly from Nicholson Street, along a terrace about 6½ feet in breadth, and raised about 3½ feet above the level of the street. In 1875 Messrs. Hastie & Co. allowed the Police Board, in levelling and forming the street, to remove this terrace, on the condition that the walls of their property were to be made secure and properly underpinned. Afterwards it was noticed that the wall next Nicholson Street was subsiding, and on March 19, 1883, it appeared, was in so dangerous a condition that, upon the order of the Master of Works, the plaintiffs were obliged to shore up the house and release the tenants from their obligations. Ultimately, the entire gable wall had to be taken down and rebuilt. Messrs. Hastie & Co. maintained that the subsidence was caused through their property not having been properly underpinned when the terrace was removed, and claimed damages on account of the loss they had sustained. The Sheriff-Substitute found for the plaintiffs, with expenses, but sent the case back again for the purpose of ascertaining the amount of damages. The Board appealed to Sheriff Moncreiff, who dismissed the appeal and affirmed his substitute's decision, and decreed that the plaintiffs were entitled to additional expenses. His Lordship says that the proof in the case is so voluminous, and the conflict of the evidence of the builders examined (many of them men of well-known ability and experience) is so great, that it is not without considerable hesitation that he has arrived at his decision. It is quite clear that the Police Board admitted in 1874 that Messrs. Hastie had certain rights, whether of property or otherwise it is immaterial to inquire, in the terrace which lay between what is called the Kilblain Street property and Nicholson Street. It is also clear that the Messrs. Hastie consented to the terrace being removed only on condition that the walls of their property were made secure and properly underfooted. It is proved that the Board undertook to make the walls secure and to underfoot them properly, and that the plaintiffs were not consulted as to the manner in which the work was done, or as to the sufficiency of the precautions taken. The Board undertook the whole responsibility, and had the house specially watched for years after the work was done. The next question was whether the work of underpinning was properly done. The Board contracted for the work with a builder of the name of M'Lure. They seem to have been unfortunate in their selection, because it is admitted on all hands that, to put the matter in the most favourable light, M'Lure was not fit to be entrusted with the work unless he was carefully watched. In point of fact, the underpinning in question was the last piece of work with which he was entrusted by the Board. Now, under the specification M'Lure was bound to underpin the remaining wall to its full breadth of about three feet; but when the work was examined in 1883 it was found that he had only underbuilt it to an extent ranging from nine to fourteen inches. It is also proved by a number of the plaintiff's witnesses that the underpinning was not built hard up against the clay, into which water had percolated. It is quite true that some of the Board's witnesses say that they did not observe any such cavities, and it is possible that there were none at the points inspected by them. But this negative evidence cannot stand against the positive evidence of the plaintiff's witnesses, and the one witness for the Board admits that if spaces had been left at the back the underpinning would not have been sufficient. It is to be observed that one result of this departure from the specification was that the contractor pocketed upwards of 10*l.*, being the difference between the price of the work contracted for and the work done. The Board, however, boldly maintain that the plan adopted by the contractor and sanctioned by them was the best and safest. The Sheriff is of opinion that the weight of the evidence, which is in accordance with common sense, is to the opposite effect. He cannot doubt that the general rule is that underpinning should at least be done to the full breadth of the wall underpinned; and although the Board's witnesses say that the amount of underpinning necessary is a question of circumstances, they do not say that they ever before saw underpinning done in the same way in similar circumstances, that is, where there was both vertical and lateral pressure to be resisted. The truth is that the removal of the terrace was an extremely risky operation, looking to the age of the buildings and the height of the bank on which they stood. It may be doubted whether it was safe to remove the terrace at all. It was certainly necessary that if it was to be removed extra pre-

cautions should be taken to make the retaining wall secure. The next question, which runs into the one just considered, is whether M'Lure's defective work was the cause of the injury complained of to the plaintiffs' property. If it was established that the work was done negligently, the burden is upon the Police Board to show that the injury to the gable resulted from some other cause. On this point there is a great conflict of evidence; but there are certain matters proved, which, in the Sheriff's opinion, are sufficient to turn the scale in favour of the plaintiffs. It is proved by the defendants' witness, Robert Benson, who sold the Kilblain Street property to the plaintiffs in 1873, that although the tenement was old it was then good and substantial. He states that there was a crack in the wall facing Kilblain Street near the corner of the east gable, but that it did not become worse while he retained the property. Now, immediately after the removal of the terrace this crack widened so much as to alarm the tenants and to lead to their presenting a petition in the Sheriff Court in November 1875, against their landlords, and the Board, for the purpose of having them ordained to make the building safe. It seems to have been conceded on all hands in that process that the widening of the crack was due to the removal of the terrace and the operation of underbuilding, but it was maintained, and successfully, by the Board that the underbuilding had settled, and that there was no imminent danger to the inhabitants calling for the interference of the Court. The Sheriff thinks he must hold it as proved that the widening of the crack in 1875 was the direct result of the Board's operations. The importance of this fact will be seen. The question, then, comes to be whether, when, in 1882, this same crack is found to have become dangerously wider, it must not, in the absence of clear proof to the contrary, be held that its widening resulted from the same cause as in 1875. The Board endeavour to account for it in every way except by referring it to their operations. The age of the building, the vibration of the plaintiffs' machinery, the percolation of sewerage about the foundations, and the reconstruction of a drain in the adjoining close, are all suggested as the true or probable causes. The Sheriff has carefully considered the evidence as to all of those alleged causes, and he does not think that, taken separately or together, they are sufficient to account for the subsidence of the east gable. The age and condition of the building may be elements to be taken into consideration in fixing the amount of damages; but looking to the fact that before the Board's operations there were no signs of the gable giving way, its age cannot be regarded as being in itself the cause. At the debate before the Sheriff the Board did not maintain that the vibration of the machinery had anything to do with the matter. The theory which was most urgently pressed was that, owing to the condition of a drain running from the back of the tenement to Nicholson Street, or to the reconstruction of that drain in 1882, the foundations of the east gable had been weakened. The Sheriff has read the evidence on this point more than once; but looking to the lie of the ground, and the relative positions of the drain and the gable, he is not satisfied that the gable could have been affected by the drain in question or by sewerage escaping from it. The point in the case as to which the Sheriff has felt most difficulty is that there were apparently no signs of fissures in the clay which is said to have subsided. The Board's witnesses say that they would have expected to have found such fissures had the retaining wall given way, while the evidence for the plaintiff is to the opposite effect. But in corroboration of the latter there is the important fact before noted, that in 1875 there must have been a slight subsidence, as the gable was affected by the defendant's operations, and yet no fissures appeared. The amount of damages was fixed at 260*l*.

### BRICK WALLS FOR STEAM-BOILERS.

THE report of the chief engineer (Mr. Henry Hiller) to the directors of the National Boiler Insurance Company, contains much practical advice which is worthy of attention from the owners of boilers. During the past year no fatal or destructive explosion occurred among the large number of boilers insured and inspected by the company; but some were injured by overheating, arising from deficiency of water due in most cases to mistake or neglect of attendants. Mr. Hiller insists on the importance of having boilers properly prepared for the thorough examinations which the inspectors of the company are anxious to make at intervals of from twelve to eighteen months, and for that purpose care should be taken in constructing the brickwork in connection with the boilers. A serious risk is incurred through the plates of boilers becoming thinned by external corrosion, and some of the most serious disasters on record have arisen therefrom. This is a preventable defect, and may be entirely avoided, providing the boiler is well made, judiciously set, and managed with ordinary care; whilst due access to every part for complete thorough inspection at suitable intervals is essential, so that any defects which may exist may be detected and made good.

The plates in a large number of boilers were found seriously weakened in contact with brickwork; this, as usual, frequently occurring at and about the blow-out pipe attachments, many of which are still met with buried in broad brickwork, which pre-

vents their being examined and leakage being detected. When cross walls are built at the front end of the external flues of boilers of "Lancashire," "Cornish," and similar constructions, so that the joint may be visible, and the brickwork in contact with the plates is narrow, serious corrosion is not likely to pass undetected. In a number of instances the corrosion of the blow-out pipes hidden by brickwork involved stoppage of the boilers at inconvenient times. This would have been averted had these parts been properly arranged to permit examination. Other cases of dangerous corrosion occurred on the cross-walls, through slaking ashes at the front of the boiler—an objectionable practice, which is yet very common, and always liable to lead to injury of the boiler, especially where, as in some cases, the floor line is above the lower part of the end-plate, when it and the portions of shell adjacent inevitably suffer from corrosion, and expensive repairs become necessary. By the use of an iron barrow or other suitable receiver of the ashes from the furnace the practice referred to can be entirely dispensed with.

The most dangerous corrosion was, as usual, met with in contact with the seatings, especially where these were of excessive breadth. In one instance two "Lancashire" boilers were found dangerously thinned on the broad side seatings, and almost all the plates in contact therewith required renewal. In a number of cases when the brickwork in contact with plates was removed by request of the inspector serious thinning was detected. In some of these the corrosion was due to the boilers being imperfectly protected from the weather, either having a defective roof or none at all over them. In one instance the back end plate and angle iron of a "Lancashire" boiler were seriously reduced, and extensive repairs requisite through the above omission.

The inspectors often meet with considerable opposition when they suggest the removal of heavy brickwork in contact with the plates, either at the seating or at the upper part of boilers, or in order that flues may be rendered accessible, and the thorough inspections which are necessary to safety made; but in many cases where this course has been adopted the plates have been found most dangerously thinned. There is little doubt that timely discovery of defects averted explosion, whilst the state of the plates demonstrate that the face of any brickwork in contact with the plates of boilers should be as narrow as possible, that all flues should be accessible or be so arranged that the boilers can easily be thoroughly examined, and that all parts should be efficiently protected from external moisture.

Many parties hold erroneous ideas respecting the construction of brick flues. A very large proportion of the boilers used in this country are set in brickwork, but in many instances this is so badly arranged that the boilers cannot be completely examined, and their condition is a matter of mere conjecture; and corrosion frequently goes on at parts of the boiler which cannot be reached and examined, often involving disastrous explosion with destruction of life and property. Contracted flues not only prevent examination but also proper cleaning. The plates of the boiler become thickly coated with soot, and the flues are of such limited area that the draught is rendered defective; but if the boiler happens to be connected to a good chimney, and the draught is fairly good, the heat passes through the flues into the chimney at a rapid rate, and has very little heating effect on the boiler. A plan has recently been strongly urged upon public attention, and adopted by a number of firms, in which the flues are made very large and roomy, and although this may not have fully answered the expectations of some who have adopted it, or the claims of those introducing it, it has doubtless proved very advantageous in some instances where it has replaced defective contracted flues.

### LEGAL.

Supreme Court of Judicature.—Court of Appeal.—June 27.

(Before Lords Justices BAGGALLAY, COTTON, and LINDLEY.)

BARLOW *v.* THE VESTRY OF ST. MARY ABBOTT,  
KENSINGTON.

THE LINE OF FRONTAGE.

This was an appeal from a judgment of Vice-Chancellor Bacon restraining the defendants, the Kensington Vestry, from proceeding to enforce an order of the Hammersmith police magistrate made under section 75 of the Metropolis Management Amendment Act, 1862 (25 and 26 Vict., c. 102), for the demolition of so much of the plaintiff's house at the corner of the Kensington Road and De Vere Gardens as projected beyond the certified building line of De Vere Gardens. In 1875 the plaintiff became the owner of land in Kensington fronting north on the Kensington Road, nearly opposite the Broad Walk in Kensington Gardens, and bounded on the south by Canning Place, the Kensington Road frontage being then occupied by a small confectioner's shop, a public-house named at the time of the Great Exhibition of 1851 "The House of Call of all Nations," which occupied the space now forming the top of De Vere Gardens, and by the entrance of the Victoria Hunting Grounds. The plaintiff shortly after his purchase applied for and obtained the approval of the Metropolitan Board of Works to the formation of a new street, 58 feet wide, running across the land

from Kensington Road to Canning Place. This new street was called De Vere Gardens, and on the east side houses were built facing the street, and having a continuous line of front. On October 18, 1881, the building line of De Vere Gardens was defined by the certificate of Mr. Vulliamy, the superintending architect to the Metropolitan Board of Works. At this date the site at the north-east corner of De Vere Gardens was being built upon, and the house erected by the plaintiff which fronted the Kensington Road and abutted on De Vere Gardens projected 7 feet beyond the building line of De Vere Gardens. This house was nearly finished when the defendant vestry took proceedings under the Metropolis Management Amendment Act, 1862, section 75; and on January 24, 1882, Mr. Sheil, one of the metropolitan police magistrates sitting at Hammersmith, made an order, on the application of the vestry, for the demolition of the house to the extent of 7 feet from the inner line of the pathway in De Vere Gardens, and parallel therewith, so that the same should no longer be beyond the general line of buildings in De Vere Gardens. The plaintiff, who had sold the house in question to one Elsdon, and then taken a mortgage for a part of the purchase money, had in February 1883 obtained from Vice-Chancellor Bacon an injunction restraining defendants, the Kensington Vestry, from demolishing any part of the premises, his Lordship holding that the frontage of the plaintiff's house was in the Kensington Road and not in De Vere Gardens, so that it was not subject to the regulations of section 75 of the Metropolis Management Act, 1862, with regard to the general line of buildings in De Vere Gardens, and accordingly that the order of the Hammersmith police magistrate was *ultra vires*, and could not be enforced. From that decision defendants, the Kensington Vestry, now appealed.

Lord Justice Cotton, after stating the case, said that one question was whether the plaintiff's house was a "building, structure, or erection" within the meaning of section 75 of the Metropolis Management Amendment Act, 1862, which had been construed in "Lord Auckland v. the Westminster Local Board of Works," L. R., 7 Ch. App., 597, to apply only to buildings, &c., built or erected for the first time. No doubt the public-house called "The House of Call of All Nations" occupied a small portion of the site covered by the plaintiff's house, which was built upon what had formed part of the garden of the public-house covered with a trelliswork. But, in his opinion, this was a house built *de novo* for the first time upon what was at the time vacant ground, and not a mere rebuilding on the site and in right of a house or houses, as in Lord Auckland's case, which had previously occupied the same site. When the public-house was pulled down the ground became vacant ground, and all rights attaching to the public-house in respect of the building line were gone. The case, therefore, fell within section 75. It was then to be considered whether this was a building or house situated in De Vere Gardens, the plaintiff's contention being that it was a house in the Kensington Road, and not in any sense situated in or subject to the building line of De Vere Gardens; and in support of this contention it was said that a house could not be physically in two streets. This, however, was a fallacy. It was clear that houses might be partly in one street or square and partly in another, though referred to for matter of description as being in one only, and in this case, although as a corner house the house in question fronted upon and for purposes of description would be described as in the Kensington Road, it was also a "building, structure, or erection" in De Vere Gardens within the meaning of section 75. In his opinion, therefore, it was a new house built for the first time, with a portion of it in De Vere Gardens projecting beyond the main line of De Vere Gardens as defined by the general line of building sanctioned by the superintending architect, and the order of the Vice-Chancellor must, therefore, be discharged with costs, both here and in the Court below. The order, however, would not be drawn up for six weeks in order to allow the plaintiff himself to make the required alteration in the house in question.

Lords Justices Baggallay and Lindley expressed their concurrence.

#### Court of Session, Edinburgh.

(Before LORD KINNEAR).

BRUCE MILLER v. WM. HOLMS AND OTHERS.

AN ARCHITECT'S BUILDING SPECULATION.

The plaintiff or pursuer in this case is an architect in Renfield Street, Glasgow, and he sued Messrs. Wm. Holms, 40 Drumsheugh Gardens, Edinburgh; Archibald Campbell Holms, Hope Park, Partick; and John Holms, M.P., for Hackney, for 1,600*l.*, which he alleged was due by them to him. His statement was that by a minute of agreement entered into between him and the defenders, of date March 13 and 14, 1882, the defenders sold to him certain plots of ground situated near Govan Church, Govan, and agreed to assist in building upon the ground by giving him advances equal to 75 per cent. of the cost of the work executed, the sums so advanced to be repayable within six months after the completion of the tenements. The pursuer states that the advances made by defenders to him amounted to 5,750*l.*, and that having repaid the sum of 7,350*l.*, he had overpaid them the sum of 1,600*l.*, which they refused to return. The defenders averred in

answer that they had from time to time made advances to the pursuer, of which there was a balance of more than 12,000*l.* still due to them, and that the pursuer, on each advance being given, granted a promissory note at six months' date for the amount, and renewed the notes for other six months, when they fell due. They pleaded that the sum sued for having been paid to them at a time when they were creditors of the pursuer in a much larger amount, they should be assolvied. The pursuer explained that the claims put forward by the defenders in this action were wholly for advances in connection with other two feuing agreements, which were entirely separate transactions from the agreement founded on, and that the defenders were now in possession of the properties built upon the ground mentioned in these two agreements.

In dismissing the action, his Lordship held that the question of accounting was not properly raised here, and the action, so far as appeared on the record, was irrelevant. It was open to pursuer, however, to bring an action of count and reckoning.

#### NEW BUILDINGS.

**The Earl of Crawford and Balcarres, LL.D., F.R.S., F.R.A.S.**, last week publicly laid the foundation-stone of a large drill-hall at Wigan, 131 feet by 75 feet, for the 4th L.R.V. Messrs. Isitt & Verity, of Bradford and Wigan, are the architects. The cost is about 3,000*l.*

**Birmingham.**—A new soap works has recently been completed at Bissell Street, Birmingham, for Mr. John Pickering, from designs by Mr. Oliver Essex, A.R.I.B.A., of Birmingham. Messrs. Whitehouse & Jones were the contractors, the boiler, steam pans, tanks, &c., were supplied by Messrs. Thomas Piggott & Co., and the steam fittings by Messrs. M. J. Rice & Co., all three firms of Birmingham. Total cost, nearly 3,000*l.*

**Ryton-on-Tyne.**—The Ryton (Parish) Local Board are just completing their new cemetery works, at a cost of near 4,000*l.* Messrs. Salter & Lishman, of Ryton, are the contractors, and the works have been carried out from the designs and under the superintendence of Mr. J. D. Lish, architect, Newcastle-upon-Tyne.

#### GENERAL.

**Mr. Watts's Equestrian Figure of Hugh Lupus**, Earl of Chester, is to be placed in the open space at the west front of Eaton Hall.

**Mr. Arthur B. Plummer, A.R.I.B.A.**, Newcastle-on-Tyne, has been appointed architect for the new church of St. Jude, to be built in the district of Shieldfield.

**The Design by Mr. A. E. Davies Colley**, of Manchester, for the Hulme Boys' School, has been adopted by the Governors on the recommendation of Mr. E. R. Robson.

**An Exhibition of Plate, Jewellery, Art Metal-work, &c.**, was open during the week at 30 Cadogan Square. The proceeds are to be applied to the Girls' Friendly Society.

**A Memorial Window** is to be erected in Westminster Abbey, in recognition of the services rendered to engineers by the late Sir William Siemens. The cost will be about 800*l.*, and is to be derived from subscriptions of one guinea.

**Mr. B. T. Batsford** has issued a new catalogue of fourteen hundred works relating to architecture, sculpture, painting, and decoration. It is so arranged as to allow of ready reference, and, as the works are selected with care, it forms a handy guide to English and foreign professional literature.

**Mr. Henry Carr, C.E.**, delivered a lecture on "Domestic Poisons" on Monday at the Health Exhibition, in which he explained the dangers arising from the presence of arsenic in wall-papers and domestic fabrics, to prevent which a Bill had been drafted the provisions of which were not more stringent than those already in force in Germany, Sweden, and other countries. Several specimens of paper-hangings were exhibited in pairs representing arsenical and non-arsenical colours of very nearly the same shade.

**Association of Municipal and Sanitary Engineers and Surveyors.**—The annual meeting of this society commenced on Thursday at Newcastle-on-Tyne. The programme included papers on "Inspecting and Testing the Sanitary Arrangement of Houses," by Mr. J. P. Spencer; "Steam on Tramways," by Mr. James Hall; "Sewage Disposal," by Lieut.-Colonel Jones; "The Cost of Local Government and the Distribution of Funds," by Mr. F. S. Brunton. It is proposed that henceforth civil engineers holding chief municipal appointments in Scotland and Ireland, in the Colonies, or foreign countries, shall be eligible for election as members.

**Mr. Benton Gibbs**, St. James's Works, Mill Street, Liverpool, was awarded the silver medal for his patent heating apparatus exhibited at the recent Agricultural Show, Birkenhead.

**The Foundation-stone** of the public baths which are being erected from the designs of Mr. Lawrence Booth, of Manchester, for the Salford Corporation, at Pendleton, was laid on the 26th ult.

*Harmony Welcoming the Nations*  
By M<sup>rs</sup> Charles Joseph Lamora

# SUPPLEMENT

TO THE

# ARCHITECT.

LONDON, JULY 5, 1884.

## THE INTERNATIONAL HEALTH EXHIBITION.

THE Health Exhibition may now be considered to have become as perfect as the projectors anticipated. The opening of the new building of the City and Guilds of London Institute has added a new and important feature to the exhibition, and both within the building and in the grounds there are novelties to satisfy the most exacting visitor. The fine weather has enabled large crowds to enjoy the evening promenade and listen to the competition between the German and English bands. There is of course a tendency to convert the exhibition into a mere show, but it would be a bad return to make the exhibitors for their trouble and expense. There is now an opportunity at South Kensington to study sanitary appliances such as may never again arise, and in the hope that it may be turned to account we continue our notes on the most useful among the exhibits.

*Mr. George M. Hammer.*

The exhibit of Mr. GEO. M. HAMMER, 370 Strand, the extensive manufacturer of school fittings and furniture, in the Albert Hall, is the largest in these classes, and would have been still more comprehensive had space been obtainable. Mr. Hammer has for some years devoted much time and thought to the question of school furniture, and has made it a complete speciality, attaching it to his other branch of manufacture, that of ecclesiastical furniture, with which it works in an harmonious manner. Taking the exhibit as he intends it to be illustrated, we have furniture for the infants, consisting of low desks and seats, formed so as to be the best adapted for writing for children of such tender years, as well as for Kindergarten work, and there are Kindergarten tables made to slope, useful alike for child or teacher. The second grade fittings are for children who have advanced beyond the infant stage, and consists of desks and seats with backs convertible in the most easy manner into tables. While giving sufficient room for school work, there is nothing in their construction to induce children to lean forward, their bodies being kept in an upright position, but with a "rest," so to speak, at front as well as back. Advancing to the third grade of pupils, Moss's dual desk and seat is the one made use of, Mr. Hammer being the sole proprietor and maker of the invention. This appliance is in use in the London schools and in a large number of School Boards throughout the country, and we are informed that nearly a quarter of a million have been sold up to the present time, which is alone a sufficient guarantee to warrant us in speaking of it in terms of high commendation. It was devised after careful investigation and study, and with the advice of eminent authorities, the aim having been to produce an article thoroughly adapted to School Board use. The desk-top presents a smooth surface 14 inches wide, free from awkward projections, with the necessary appendages of ink-wells, grooves for pens, &c. When not required for use in its normal position, the front portion of the desk-top can be thrown back to form an inclined book, music, or drawing copy rest. Ample room is also left between desk and form for drill or other exercises. A separate compartment is provided for each scholar in which to place his school materials, and these are open to the eye of the teacher. Besides the back to the form, an inclined foot-rail is fitted to every desk, affording proper rest to feet and ankles. Beyond these features the position of the desk-top has been regulated to prevent stooping, and to prevent undue pressure upon the chest. There are other matters in connection with the Moss desk and seat worthy of inquiry into by those whose requirements lead in this direction, which the prospectus published by Mr. Hammer will give them, and this brings us to consider the appliances made for high-school teaching. Here separate desks

and seats for each pupil are the approved plan, and we are shown the "Louise" for girls and the "Albany" for boys. These are made to slide for girls, enabling free egress or ingress to be obtained, and for the boys the seats turn up to a level with the back for this purpose. An engraving of one of these

is here given. Miller's class drawing models, as adopted by the Science and Art Department at South Kensington, are also shown in complete sets, and a selection of smaller models also, all of which are manufactured by Mr. Hammer. Then we have a variety of different pattern drawing-desks, and tables and desks for teachers, &c., of the most approved construction. Amongst the latter the visitor can scarcely fail to notice a finely-marked table of polished pitch pine with drawers and cupboard, which will repay a few minutes' inspection. In the new Technical College in Exhibition Road, Mr. Hammer has sent a collection of school fittings as used in the college at Ealing for the education of the deaf and dumb. These are made in the form of segments of circles, in accordance with the mode found by experience to be best adapted for those poor sufferers. In the iron building erected adjoining the exhibition as a test-house for the jurors, in prosecuting their examinations of the different foods, &c., on which they have to adjudicate, Mr. Hammer has lent the whole of the required fittings, such as fume-closets, microscopic tables, &c., and he may fairly be said to be a most important contributor to the exhibition.

*The Indestructible Paint Company.*

At 870 the INDESTRUCTIBLE PAINT COMPANY, 27 Cannon Street, are exhibiting that valuable preparation known as Browning's patent invisible preservative solution, and also Browning's patent enamel paints. The important advantages of the solution, which is unequalled for coating stone, marble, brick, cement, plaster, &c., can scarcely be over-estimated, for the materials coated with it are not only rendered effectually damp-proof, but, what is of equal if not more importance in the case of stone and marble, are quite secure from the deleterious effects of an atmosphere surcharged with carbonic acid and sulphurous vapours as that of the metropolis and other large cities is. Mention has been made on previous occasions in the columns of *The Architect* of important works in which it has been used, amongst them being Cleopatra's Needle, and though more than five years have elapsed since the solution was applied to it, a recent examination shows it to be as clean and fresh as when it first took up its abode in this

murky atmosphere. An example of the waterproof virtue of their enamel paint is seen on a specimen of plaster that came away bodily from the wall of the Ocean Marine Insurance Offices, that, being damp, had been coated with it, but instead of the moisture causing the paint to perish or otherwise damaging the surface, the paint stood its ground, and the water, as we have mentioned, found other means of exit. Some very delicate tints are shown which meet the demand for the neutral and low tones so much in vogue.

*Mr. Ellison.*

At Stand No. 717 Mr. ELLISON, Victoria Square, Leeds, has taken up his position, and is showing his patent "Conical" and patent "Radiator" ventilator, and the patent exhaust ventilators and chimney-tops known as Stevens's patent. The principle of the conical ventilator is applied chiefly to perforated bricks and air-grates, and as such forms the most perfect of the kind in the market. These air-grates are constructed with conical or wedge-shaped openings tapering larger to the inside, by which means the incoming current of air is so effectually radiated and diffused that draught is avoided. The same principle is seen in the "Radiator," of which we give a sketch, though its construction is different. It

is composed of a flat disc, having behind divisions placed cross-ways, which on closing the ventilator, slide into a box fixed in the wall. These divisions form, as it were, wedge-shaped compartments, and so disperse the incoming air in all directions, and effectually prevent any draught. The amount of air to be passed through is easily regulated, and they can also be supplied with screw movement and loose key for public institutions. The following sketch depicts Stevens's patent exhaust ventilator, also made

by Mr. Ellison. This is a very simple and efficient apparatus, and is so well known that but little comment from us is necessary. As will be seen from the engraving it is of the fixed kind, and is so constructed that at whatever angle the wind strikes the cone, a partial vacuum is created in the chamber under the hollow cap, and a powerful upward current secured.

*Messrs. J. L. Bacon & Co.*

At 1,137 Messrs. J. L. BACON & CO., of 34 Upper Gloucester Place, Dorset Square, N.W., are showing in action their system of heating and ventilation, and will well reward examination. Most of our readers are aware from previous allusions in the columns of *The Architect* that this firm were the first to introduce a tube of special diameter and thickness, of which our illustration gives a view. The apparatus consists of these specially-manufactured wrought-iron tubes, the strength and flexibility of which is shown by a coil surmounted by a double knot of pipe, on which there is a gauge, showing a constant pressure, on the whole, of 4,000 lbs. per square inch. The tubes are provided at the ends with right and left-handed screws, and are connected together by means of sockets similarly screwed, which draw the ends together and force them

one into the other, making a perfectly sound hydraulic joint. This joint is not at all affected by expansion, and offers the further advantage of allowing any tube to be disconnected and removed without the least disturbance to the rest. The larger portion of these tubes form the heating surfaces and connections of the apparatus; the remainder, an exact and fixed proportion, built in a furnace at the lowest level, takes the place of the ordinary boiler. The apparatus, therefore, consists of an endless circuit of tubes, all of the same diameter. The most important advantages of this system are ease of application, durability, heating capacity, and incongealability. The first three are brought about by the method of fixing the apparatus and the special make of the tubes, as already described; and the latter is due to the substitution of a patent non-freezing solution for ordinary pure water. This overcomes the necessity of maintaining fires during excessive cold, whether otherwise required or not, to prevent the water in the pipes freezing; and, in addition, the solution once in the tubes serves for an indefinite period without losing its effectiveness, since it neither decomposes, precipitates, nor evaporates under the action either of heat or cold. The specimens of coil-cases and ornamental gratings are of excellent design, and show how the apparatus can be made a handsome addition to the decoration of a house. Besides these Messrs. Bacon & Co. show several methods of applying their apparatus to schools and other public buildings, as well as plans of buildings they have heated and ventilated, from which we gather their system very readily adapts itself to any kind of structure. Among the systems of ventilation this firm carry out is one that is largely adopted on the Continent for large buildings, and consists in extracting the vitiated air by means of a fan worked by a gas-engine, while the fresh air is warmed before entering by passing over the hot-water pipes.

*Mr. R. Adams.*

At Stand 386 are to be seen a number of appliances of which it is only fair to say that, their advantages being once known, few would be without. Mr. R. ADAMS, of 17 Blackman Street, Borough, S.E., is the patentee of a variety of improvements in that somewhat insignificant though indispensable class of household fittings comprised under the generic term "sash-fastener." Any attempt at perfection combined with simplicity and security, not to mention automatic action, in the manufacture of these articles has until recent years been a feature much overlooked; not that we wish to deprecate the numerous patent sash-fasteners, pure and simple, that have from time to time appeared, and some of which are highly ingenious, for we refer rather to contrivances for allowing ordinary sashes or casements to be open a certain space for ventilating purposes, and which at the same time allow no opportunity of being tampered with or further opened from the outside by the burglar. Of these that deserve special mention there are shown the patent sash-bolts and ventilators, patent casement stays, patent rack fanlight-opener, patent secure fanlight-opener, and patent "Triumph" burglar-proof sash-fastener. The Norton door-check and spring, and the patent reversible and sliding window-frames should not be passed over. The special features of the former are that immediately the door is let go after opening it, it closes by the action of the spring, but quite noiselessly; should the door be slammed to, the action of closing is equally noiseless. It is brought about as follows:—The device besides the spring consists of a cylinder, piston, and self-adjusting valve, and is attached to the top part of the door and door frame. The "check" is caused by the cushioning of the piston on air, which brings the door to a stop for an instant near the jamb, then quietly closing and catching it by the operation of the spring, being regulated by the automatic valve, which permits the air to enter the cylinder freely while opening the door, and while closing exhausts the air, more or less, as the force exerted on the door to close it is greater or less. The patent reversible and sliding window is a simple method of removing the sashes from the ordinary vertical position, to facilitate their being properly cleaned from the inside; it has now been before the public for some time, and, we believe, gives general satisfaction.

*Messrs. Waygood & Co.*

At Stand 1,136, in the machinery in motion gallery, Messrs. WAYGOOD & CO., Falmouth Road, S.E., are showing their patent lifts in action. They comprise a patent hydraulic balanced passenger lift, so constructed that balance weights, &c., are dispensed with; a patent steam-power lift for passenger or warehouse use; a hand-power warehouse lift, and a double dinner lift. The hand-power warehouse lift is fitted with patent self-sustaining brake, by which the load is held stationary when the hauling rope is released, and patent safety apparatus to prevent the cage from falling in case of the lifting rope breaking. This contrivance is admirably adapted to serve such purpose, and is as simple and effectual as possible. It acts as follows:—On each side of the cage or box are securely bolted two wrought-iron plates, having in each a vertical slot in which the cross bar at the top of the cage works, and until this reaches the top of the slot, the cage is not lifted. Directly this position is reached it distends the four cams that are situated two on each side, so that they just clear the wood

or iron upright. In the event of the rope breaking the bar drops of its own weight, and is accelerated and made more sure by two strong springs upon the cams. These immediately grip the uprights, and keep the cage in suspension. The steam-power lift is worked by two driving bands, one to send the lift up, the other to lower it, which secures the utmost uniformity of action. Another advantage is, that the gearing is so constructed that the rate of speed having been once determined is not under the control of the attendant, but is perpetually adhered to. The patent self-sustaining gear can be applied to any existing lift, and from its efficiency and reliableness is well worth attention. A patent portable self-feeding drilling machine for hand or power is also shown, and appears to possess no inconsiderable advantages.

*Messrs. Le Grand & Sutcliff.*

No. 458 is occupied by Messrs. LE GRAND & SUTCLIFF, 100 Bunhill Row, with a collection of Abyssinian and artesian tube wells and pumps (Norton's patent), diving and boring apparatus, and horizontal mains, with connections, &c., for same. This is another exhibit that may be looked upon as one of the most legitimate, and is at the same time very interesting, for it is not generally known that this system is as available for supplying the smallest domestic wants as for providing the large quantity of water for town waterworks, breweries, and other manufacturing purposes. As a proof of this, we may mention that in many places where the inhabitants are dependent upon the common pump, often not sunk more than 15 to 20 feet deep, for their water supply, and where the cesspool still does duty for drainage, landlords have in several instances supplied their respective tenants with water from a depth beyond all possibility of contamination from the latter, by the use of these Abyssinian tube wells, and at a less cost than for sinking an ordinary well. This firm have always been very closely, almost exclusively, associated with this branch of hydraulic engineering, and have done much to develop it; and amongst the appliances here shown is a patent driver just recently

patented, which is well worthy of attention. As a glance at the sketch we give of it will show, it does away with ropes and pulleys, the pipes being driven by two men raising the "monkey" and striking it down on the cap, merely taking care that the pipe is kept perfectly perpendicular. The other sketch shows their horizontal mains in plan and elevation for connecting a series of tube wells, it being the most simple and effective method of conveying a large supply of water to one reservoir or receiver.

*Messrs. Bowes, Scott & Read.*

Mr. Roger Field's syphon flushing tank, in model, is exhibited by Messrs. BOWES, SCOTT & READ, Broadway Chambers, Westminster, and the self-acting annular syphon is shown in connection with a flushing cistern holding 1,100 gallons. Mr. Field's flush-tanks in cast iron and earthenware are, in addition, on the stand. The firm's patent latrines in enamelled earthenware, salt-glazed ware, and cast iron, and their enamelled earthenware trough-urinal, all fitted with Field's syphon for automatic and periodic flushing, form an exhibit worthy the attention of all public authorities or large employers of labour. The principle of Mr. Field's syphon is so well known to the profession and builders generally that further details respecting it would be superfluous.

*Mr. P. A. Maignen.*

Mr. MAIGNEN, of Great Tower Street, plays an important part at this exhibition, not only as an exhibitor, but as an administrator to the comforts of those who are "athirst," and can satisfy themselves with a draught of the "pure pellucid stream," for in various

parts of the grounds he has erected tasteful little edifices, forming water filters on a large scale, on the principle of his "Filtre Rapide," from which pure fresh filtered water is constantly dripping. In another part he has erected a village pump, so arranged that every drop drawn shall be filtered; and attached to this is a balanced tip-up trough for horses and cattle, the water that is admitted to this being also filtered. The advantage of the tip-up trough is that, when an animal has drank, the balance-weight will overturn the trough, and so empty it every time it is used, which provides for a fresh clean draught for the next comer. That this filter is gaining a popularity never reached by any other is quite patent, and the extraordinary changes he effects with various liquids after passing them through his filter is extraordinary. Wines and chemicals of various colours are rendered perfectly white and tasteless, and in one instance we saw a mixture of sewage water and acetate of lead returned to the glass clear and sparkling, which was drunk by one of his assistants. These filters are made to suit all requirements. The appended illustration represents a domestic filter, showing a portion of the interior. All the parts are loose, and each can be taken out for cleansing. The following is the mode of arranging the filtering media, which is composed

partly of fine powdered charcoal and partly of granular. An earthenware perforated cone has a cover of asbestos cloth, the reservoir holding the unfiltered water, in which this is placed, being partly filled with granular charcoal. This reservoir is nearly filled with unfiltered water, and the necessary quantity of fine powdered charcoal is mixed with some water and poured into it. Filtration now begins. The contents of the reservoir and entire black mass gradually pass through the asbestos cloth, leaving the charcoal in the form of a compact coating on the asbestos. The granular charcoal arrests all the heavier bodies that the water may contain, and whose weight would carry them downwards, and the smallest living organisms are prevented from passing through the covered cone, which is the only inlet to the reservoir for filtered water. Mr. Maignen also aerates the water by providing a tube through the centre of the filter to the lower reservoir, and the insertion of a small portion of cotton wool in the top of this tube secures the purification of the air so entering, and prevents dust, &c., from entering. In the ambulance department Mr. Maignen shows the different specimens of his filters suitable for the camp, or an army on the march, which have been adopted by the War Office, and have lately been used in the Egyptian campaign, and in this direction his invention is likely to prove a great boon. But the inventor aims at still higher gain, and has demonstrated clearly that by means of his system of filtration he can filter the entire water supply of the metropolis, or any other town, more effectually, at a much smaller cost, and with a mere minimum of space as compared with what is now required by the different water companies; in fact, the system has been tried on a small scale by one of the London companies with very satisfactory results. At his stand in the south gallery he exhibits a large drawing, illustrating the principle on which he bases his ideas. Should this ever be carried out in accordance with Mr. Maignen's views, it would be the means of liberating a large amount of land now used by the companies as filter beds, which they could utilise for other purposes, even for building upon, which would return them a considerable income.

*Messrs. Crouch & Jay.*

At 442 Messrs. CROUCH & JAY, of Maroon Street, Limehouse, E., are located, and contribute a very useful though an uninteresting looking collection of galvanised and patent wrought-iron cisterns

and tanks. In these days when modern villas of the most ordinary description are fitted with hot and cold water service to the bathroom, there is a large and constant demand for such articles, especially for the hot-water circulating cylinder; so that it is very necessary to know where thoroughly reliable and carefully-tested apparatus can be obtained, as explosions are as often due to the inferior quality of these as to other causes. Messrs. Crouch & Jay's goods being well made, and turned out at a very moderate price, are in large demand; they nevertheless hold a considerable stock at the above works, and can execute the orders the day afterwards.

*Messrs. Bolding & Sons.*

At Stand 539, east annexe, Messrs. BOLDING & SONS, South Molton Street, have contributed a collection that tends materially to render this section a complete and representative one. The exhibit comprises one or two handsome baths, fitted in rich and elegantly carved cabinet-work, and with the firm's new registered bath levers; a large variety of closets in different qualities, including the "Simplex," Grosvenor, and Argosy "valve" closets, the National, and the Crown "wash-out" closets; a selection of hot water-cocks, fire-cocks, hose pipes, hose unions, and other water fittings; drawn lead traps and other plumbers' fittings, including some remarkable specimens of the skilled plumbers' handicraft, in the shape of lead piping bent into traps, &c., and a patent "Bottle" trap. This trap is specially suitable for kitchen and butler's pantry sinks, as it effectually prevents the escape of sewer-gas, and the seal is so complete that it cannot be broken by syphonage. The dip can

"SYPHON" WATER WASTE PREVENTER

be removed at will to facilitate unstopping, while a cup is provided to prevent any foreign matter passing into the pipes. The diagram which we give represents Bolding's seat action, syphon water-waste-preventer flushing cistern. The salient feature of this, and the difference between it and a similar one the firm make is, that when the seat of the closet is depressed the lever is drawn down, but upon the user rising, the weight of the lever falls and opens the valve, when the water is discharged with such a force through the syphon as to thoroughly wash away the contents of the pan. In addition to this display in the eastern annexe, Messrs. Bolding have a special collection in the water companies' court of goods, some of the companies largely using their make, a fact that speaks very significantly for the reputation in which this firm's work is held.

*Messrs. Steel & Garland.*

This firm, of the Holborn Viaduct and Sheffield, are in close proximity, and have been fortunate in securing two stands. The exhibit, like the others before named, consists entirely of suites for the fireplace. The mantelpieces here are of marble and wood. Amongst the latter we may mention a black ebonised mantel and over-mantel, the slab underneath the mantel-shelf being composed of panels in bronze representing the seven ages of man, and by the side of this, bringing both suites out to the best advantage, is a charming Sheraton mantel and over-mantel, with a dog grate, and the usual accessories. The grates connected with smoke consumption are the now well-known "Wharnclyffe" and the "Kensington," shown for the first time at the Smoke Abatement Exhibition, and which was awarded the gold medal.

*Messrs. Wilcock & Co.*

Just behind Doulton's pavilion, on the left hand side, will be found the attractive exhibit of Leeds faience contributed by the well-known firm of WILCOCK & CO., Burmantofts, Leeds. This exhibit consists of architectural faience for decorative purposes in construction, and a great variety of independent, ornamental articles for domestic decoration, amongst which vases and stands form a commendable portion. Elegant mantelpieces, fireplaces, kerbs, &c., comprise another section, and there has been built up a noble porch with circular roof, that is of itself worth a visit to this stand, and it is almost unnecessary to add that the workmanship is of a high order of merit, and the colours of fine tints. Any person who has had the advantage of going over Messrs. Wilcock's works cannot but bear testimony to the care employed in the manufacture of all their productions and the skill of the artists employed in the decorative departments. But apart from the artistic features which, in a very few years, have won such a

reputation for the firm, Messrs. Wilcock & Co., are quite capable of holding their own in the common kinds of clay goods, their bricks both plain and colour glazed, being equal to anything of the kind made. Blue bricks are also a speciality, and are made of a particular mixture of clay, fashioned by hand, and fired at a welding heat. Their drain-pipes and other sanitary ware are well known to be, both as regards quality of clay and general manufacture, second to none in the market. One of the best productions in this class of goods, of which a sample is shown, is Holroyd's patent glazed stoneware trough closets or latrines, of which we give an illustration, intended for the use of schools, factories, and kindred places where large bodies of people are

daily congregated. They are made of fine, glazed stoneware, open throughout along the bottom, and are flushed at periodic times by means of a large, syphoned cistern, which sends such a powerful body of water along the channel that every atom of solid matter is entirely carried away to the drain at each flush. With the walls built up of glazed bricks, a hose-pipe can be brought into play to cleanse the entire building in a few minutes. These closets are being extensively fitted up in many parts of the kingdom.

*Messrs. Farmer & Brindley.*

Stand No. 868 is one that should be seen by all professional men as well as by builders and others, for here are gathered together, in a small space that enables a ready and easy inspection, an assortment of the choicest and rarest kinds of marble that have ever been quarried—an assortment which we believe it would be impossible to equal either in richness or variety. The exhibitors are Messrs. FARMER & BRINDLEY, Westminster Bridge Road, and when we mention that each specimen they are showing represents many tons, and in some cases thousands of tons of stock at their yard, it will be admitted that they hold a unique position. It will be obvious that any written description would fail to give an adequate idea of material whose *virtu* is dependent upon a freak of nature, and no two specimens of which are exactly alike; but we append the names of some of the kinds that more particularly impressed us, and all those who either specify or use marble, whether for columns, enrichments, wall panels, or pavements would, as we have before remarked, be making good use of their time to pay a visit to this stand in the exhibition, or the firm's show-rooms at the above address. The rediscovered "Cipollino" marble is imported solely by Messrs. Farmer & Brindley, and is represented by two beautiful slabs of the bright and dark variety. "Pavanazza" is a marble they also hold a large stock of, and the specimen shown is exceedingly rich; and less cannot be said of the samples of "Africano," and Egyptian porphyry, while the Onyx, Mexican Onyx, Crocidolite, and Labrador spar can scarcely be too highly eulogised, and are such specimens that one rarely meets with. Last, but not least, are some slabs of Tyree marble, introduced by the Marquis of Lorne, which the firm have taken up on his behalf, and as it has a good appearance, will probably soon come into general demand, though it has hitherto been little known in this part of the country.

*The Coalbrookdale Company.*

In the approach to the east gallery stands the principal exhibit of the COALBROOKDALE COMPANY, of the Holborn Viaduct and Coalbrookdale, Shropshire, the articles shown consisting of mantelpieces and overmantels in iron, grates, kerbs, and their accessories. The iron mantels and overmantels are undoubtedly the principal features of attraction here, and they form the last speciality in domestic furniture in the long list of decorative articles in iron introduced by the Company. These chaste productions first saw light at the Smoke Abatement Exhibition, held here some three years since, when their delicate lines deceived every one who saw them, and great was the surprise when the visitor was informed they were made of iron and not wood. Since that date the idea has been greatly developed, and many other patterns have been added, the talents of some of the best known designers having been secured for the work. Amongst the designs shown on the present occasion are some examples by Mr. W.

Scott Morton and Mr. R. Norman Shaw. The bulk of the designs may be said to favour what has been popularly called the Queen Anne style, but embracing also the Adams, Chippendale, and Jacobean, and, in fact, those styles that were mainly in vogue during the reigns of the Georges; but many of them are toned down, so to speak, and, if we may use the expression, of a more modernised appearance. They are painted in low-toned colours or neutral tints, and one of their great recommendations is that, notwithstanding their high artistic worth, their cost is considerably less than that of any other material. The grates consist of the various patent ones made by the Company, and include the Whitwell "save-all," the Kyrle, the Holland, Millner, and others of chaste designs not claiming any particular speciality in their general construction. As we have described most of these on former occasions we need not repeat details here. It is almost needless to add that every article displayed bears the impress of that superior finish attaching to everything that emanates from the Coalbrookdale Company's *ateliers*. In the vestibule of the exhibition are to be found a collection of their best garden seats, lent by them to the executive for the convenience of the visitors. It needs no inquiry on the part of those who have any knowledge of the finished iron productions of the country when looking at these seats, as a mere look at them will show that they carry the impress of Coalbrookdale in them; and the fountains erected by the water companies have been supplied by the Coalbrookdale Company.

*Messrs. Barnard, Bishop & Barnard.*

Adjoining the Coalbrookdale Company is the stand of this firm, of Queen Victoria Street and Norwich, who in connection with the grate trade, it will be recollected, made a great sensation a few years since with their "Parson's" or slow-combustion grate, the "lines" of which have since been adopted by other makers. Many of our readers will remember the handsome display made by this firm at the late Smoke Abatement Exhibition, and the "Glow" shown on that occasion. It is somewhat remarkable and has been brought very forcibly to our notice by a recent circular published by the firm, that this grate, which compared very favourably with others that were tested, received no award; and they naturally ask "on what ground, or by what line of reasoning could the judges arrive at their awards?" There are some very handsome suites in this exhibit, a prominent one being that designed by Mr. J. R. Pearce, F.R.I.B.A., of Norwich, for a mansion of Mr. Samuel Hare, at Cromer. The design is from Dutch decoration, and includes a dog-grate principally of wrought-iron and brass; tiles of Dutch manufacture are exclusively used, and the mantel is of teak wood, the whole presenting a unique appearance. The grates shown comprise some very handsome features, and in the smoke-consuming class will be found the "Glow," before mentioned, and a new open grate, with an angular-formed fire-basket of fire-clay with a "baffle" above it, which is said to perform its duties exceedingly well as a non-producer of smoke; but we have not yet seen it in action. The accessories connected with each of the suites evince the same good taste as in the principals, and the whole represents a very attractive exhibit.

*Mr. H. W. Cooper.*

Attempts have of late years been made to coat iron piping with glazed substances to prevent the iron from oxidising, and to keep the water or other liquids passing through them pure. The latest introduction in this direction hails from America, and takes the form of glass-lined wrought-iron piping, which is shown by Mr. H. W. COOPER, of Wimpole Street, W., at Stand 464. The advantage claimed for this piping is that, from its perfectly smooth surface, water or other liquids passing through it flow more freely and at a more even temperature, and in the same condition as when it left its source. It is also strongly recommended for chemicals. We cannot expect that piping of this description can ever be used for our large water-mains on account of its price, but there are innumerable uses, where cost is not of much consequence, to which it may be adapted with much advantage, and from a sanitary point it has much to recommend it.

*Messrs. R. Houghton & Co.*

This firm, whose address is 21 Sloane Terrace, S.W., have recently come to the front with some simple but meritorious sanitary appliances. They are patented inventions, and comprise a fat interceptor, made in various sizes, a stable gully, and another for baths, sinks, surface drains, &c. They are the outcome of long and practical experience on the part of a patentee, and serve their purposes remarkably well. No better tribute can be paid to their value when we say that in certain systems of drainage we have seen exhibited in different parts of the country, the Houghton fat interceptor and gully have been shown as part of the arrangement. The firm in addition exhibit examples of faulty plumbers' work, collected by them from different sources where they have reorganised the system of drainage, showing the fatal mistakes often made by inexperienced and unprincipled workmen. Although this collection comprises work executed years ago, when but little attention was paid to sanitary science, the firm show that we are

not exempt from similar dangers at the present day, a specimen of new work being on the stand, recently removed by Mr. Houghton from a mansion in Eaton Square, and this is widely made known as an example of the "jerry" work indulged in by some workmen of the present day. Mr. Houghton also shows several plans of works recently laid down by him; one of which, just completed at The Villa, Effingham, Surrey, is worth a few minutes' attention by any architect or builder who may pass by his stand. We shall not attempt to describe it in detail, but content ourselves in saying that the house is said to be now sweeter and purer than at any time since it was first inhabited.

*Mr. J. B. McCallum.*

The borough engineer of Blackburn, Mr. J. BRADDON MCCALLUM, A.M.I.C.E., exhibits specimens of his tipping tank waste-preventing cisterns, of which we append an illustration. These cisterns are arranged to suit all requirements. They can be applied in connection with the seat action of a closet, the pull action, or may be set to work automatically for discharging water at any given time, and are as efficacious for urinals as for closets. On reference to the drawing, the action will be understood at a glance.

It is simply poised in such a position that when the water reaches a certain level it cants over and discharges its contents in full volume. It will be seen that there is no ball-cock, outlet-valves, or syphons, and that its construction is of the most simple character. We have no objection to syphons when attached to water waste-preventers, but the tipping tank appears to us to offer the most simple mode of flushing under any circumstances, and it is difficult to imagine how it can be placed out of order, and its price should be less than in any other where mechanism is employed.

*Messrs. R. Anderson & Co.*

No. 459 is a Stand that should not be overlooked. The exhibitors are Messrs. R. ANDERSON & CO., Duke Street, Liverpool, and they have sent a most creditable assortment of high-pressure water taps and fittings, bath fittings, copper circulating cylinders, copper bath boilers, lift and force pumps, &c. In one and all of these articles it is clearly apparent that they are made for wear, though in saying this it must not be supposed that finish or appearance has been lost sight of, but as it should be, is looked upon as a subservient feature, so that we have here thoroughly sound and reliable work at a moderate price. A convincing proof of this is seen in the Liverpool Corporation Waterworks having used the fittings of the firm for the last twenty-five years. Messrs. Anderson & Co. are also showing an improved safety-valve for the prevention of boiler explosions, which is worth attention.

*The Birmingham Sanitary Association.*

At No. 479 the BIRMINGHAM SANITARY ASSOCIATION, 28 Upper Priory, Birmingham, are located. This association, situated as it is in the above town, is the principal agency in the Midlands for the most approved sanitary appliances, and is the representative in this large district of most of the leading London and other firms. In addition the association are the sole licensees for the United Kingdom of a patent trap known as "Potts's Patent Edinburgh Sewer Trap," and it is this that brings them to the present exhibition. It is shown in several sizes, and on inspection will be found to possess many unique features, amongst the most important being that it allows for the total disconnection of house drains from the main sewer, and may be said to answer the purpose of a brick-built intercepting chamber at a much less cost, while a grating which provides for the admission of fresh air to all the pipes fixed above it is of almost equal advantage. Full-size diagrams are also shown at the stand, whereby one may readily judge of its efficiency when in actual use.

## VERTICAL VENTILATING PIPES, BENDS, AND BRACKETS,

*In every Size and Design, for admitting Cold Air into Rooms without Draughts. Success guaranteed.*

In addition to the *many thousands* of the Patent Manchester Grates in use in the United Kingdom, Ireland and on the Continent, 80 have recently been fixed at the Salford Hospitals, Manchester; 70 at the County Asylum, Prestwich, near Manchester; and over 100 at the Oldham Workhouse, &c., &c.

Alexander Ross, Esq., Architect, of Inverness, writes on the 2nd of April, that he has the Manchester Grates in use at 109 Schools and Houses in Scotland.

The MANCHESTER GRATE can be applied to any design of grate front, and no grate as a heat giver is complete without it. The Manchester Grate warms and ventilates other rooms in addition to that in which it is fixed by that which is the waste heat of the ordinary grate. New book of Testimonials from all parts of the United Kingdom, alphabetically arranged, free on application.

TO ARCHITECTS.—THE BRICK of the FUTURE, that shall not get dingy or sooty like other Bricks, but, being of a **Semi-Vitreous** nature, will maintain a clean and washable surface.

## FACING BRICKS AND BRICK ORNAMENT

## TRUE TERRA-COTTA,

AS ALSO ARCHITECTURAL WORK,

## IN WHITE AND WARM-TINTED BUFF.

Made from the Finest Terra-cotta and Stoneware Clays, of a warm and pleasing appearance, of beautiful and superior quality and finish, non-absorbent, acid, fire, and alkali proof, will resist the most severe frosts, and when tested were found to withstand a pressure of 445 tons to the square foot. They have been used in the most exposed parts on the North and South Coasts, and being true Terra-cotta, are warranted imperishable.

Pattern Sheets and Price Lists of superior Glazed Stoneware Sanitary Pipes, and Fire Clay Goods, Chimney Tops, &c., on application.

Sole Manufacturers—CANDY & CO., Limited, GREAT WESTERN POTTERIES, NEWTON ABBOT, AND 11 QUEEN VICTORIA STREET, LONDON, E.C.

Who are also Sole Makers of the celebrated "Granite Vitrified" Paving Bricks for Yards, Stables, and Footpaths, and "Granite Vitrified" Damp-proof Building Bricks, as used by H.M. Government for dock construction, &c.

Samples free to Architects and Engineers.

Salisbury Cathedral is built; also used in the restoration of  
Westminster Abbey and Chapter House, Chichester and Rochester  
Cathedrals, St. Albans Abbey, many Churches, Mansions, &c.  
Price of Block, Sawn or Worked Stone, Steps, Paving, Walling  
Stone, Rough Blocks for Engineering Purposes, &c., on applica-  
tion to T. F. LILLIX, Gillingham, Dorset.

GRUNDY'S PATENT  
WARM-AIR  
VENTILATING FIRE GRATE.

The novelty, superiority, and advantage of this patent  
consist in the heating surface being greater than any  
other Fire-grate introduced to the public. It is very  
simple in construction, and is made in the form of a Stove,  
the back of which is semicircular in shape, with gills  
behind and smoke-nozzle on top, all cast in one piece.  
The same can be attached to any design of a Register or  
Stove front. It is very suitable for schools, class-rooms,  
waiting-rooms, hospitals, offices, dormitories, and dwelling-  
houses, from the cottage to the mansion. Design and  
specification post free on application.

## TESTIMONIALS.

"9 Victoria Chambers, Westminster, S.W.

"June 10, 1884.

"Sir,—I have much pleasure in testifying to the  
efficiency of your patent Warm-Air Fire Grate. It has  
been very successful, and given every satisfaction where I  
have used it.

"Yours, &c.

"JAMES WEIR, F.R.I.B.A.

"To Mr. Grundy."

"Baptist Chapel, Clapham Common, London. Richard  
Webb, Pastor, 10 Grafton Square.

"February 15, 1884.

"DEAR MR. GRUNDY,—I have pleasure in testifying to the  
excellency and efficiency of your patent Fire-Grate. It is  
the most charming invention for heating a large room I  
have ever known. I shall have pleasure in showing it to  
anyone who wish to have their schools or rooms pleasantly  
and efficiently heated."

# DE MORGAN ART TILES.

# BELL'S ASBESTOS.

## BELL'S ASBESTOS FLOORING FELT.

This article is manufactured from specially prepared Asbestos fibre, and by its use any building can be rendered comparatively fireproof at a very small cost. This material should be used as a substitute for brown paper under the carpet, and it can be taken up and relaid as often as required; it may be laid between the flooring boards, on the ceiling before plastering, and on the walls. Doors of pine or other wood should be so constructed as to have a sheet of the felt in the centre, so that either side being burned the other remains intact. In houses so protected fires would be localised to the rooms in which they originate. Asbestos felt, being a non-conductor of heat, is superior to any other sheathing, and used under slates has no equal. It yields no dust, lies quite flat, is soft to the tread, and its low cost places it within the reach of everybody. Made in rolls of 36 inches wide.

IN ROLLS OF 36 INCHES WIDE.

**BELL'S ASBESTOS BOILER AND PIPE COVERING COMPOSITION** for coating every class of steam pipe and boiler. Non-combustible, and easily applied when steam is up; adheres to metals and preserves them from rust; prevents the unequal expansion and contraction of boilers exposed to weather; covers 50 per cent. more surface than any other coating, and is absolutely indestructible. It can be stripped off after many years' use, mixed up again with 20 per cent. of fresh, and applied again. The composition is supplied dry, and only requires to be mixed with water to the consistency required for use.

**BELL'S A**

The goods of this house are attempted to be made to compete with inferior materials at low prices to the undermentioned depots,

A horizontal boiler, 17 ft. 6 in. long, 15 H.P., gave the following results:—

Temperature on Plates .. .. .	186 deg.
"    "    Covering .. .. .	94 "

One ton of coal was saved per week, and, although the fire was raked out every evening 20 lbs. of steam were in the boiler next morning.

The following testimonial refers to this covering:—

Offices of Wimbledon Local Board, Wimbledon, Nov. 28th, 1883.

Dear Sir,—It may interest you to know that we save exactly 40 per cent. in fuel through using your covering.—Yours truly,  
W. SANTO CRIMP, C.E., F.G.S.,

**BELL'S ASBESTOS PAINT**, for floors, stairs, and all interior woodwork, to prevent the spread of fire. This paint is especially useful in cotton mills, and in fact in all factories and buildings exposed to risk from fire. It is quite free from poisonous ingredients, and is both easily and cheaply applied. Bell's Asbestos Paint has, on several occasions, done great service in preventing the loss of life and property. The great fire in Buchanan Street, Glasgow, in November last, produced the following testimony to the value of this material:—

Offices of the *Glasgow Herald*, the *Weekly Herald*, and the *Evening Times*.

Mr. John Bell. Glasgow, Nov. 14th, 1883.

Mr. John Bell, Glasgow, Nov. 14th, 1883.  
Sir.—As one of the means that helped to save our buildings extending from Buchanan Street to the West, from the recent great fire, I think it fair to say that your Asbestos Paint, which was applied to the outside hoist, was the only one that was not consumed, and a valuable proof that it materially aided in resisting the flames from the immediately adjoining tenement where the fire was rapidly destroying it and threatening us in the most serious form. I placed a piece of wood, with your paint put on more correctly than in our case, into one of our furnaces, with the result that it was brought out without a fibre of the wood being touched, while similar pieces of wood, thrice coated with Irish Lime, at once became a flame, and were truly

(Signed) ALAN BELL, M.R.S.

**BELL'S ASBESTOS SASH-LINE CORD** is unaffected by heat and damp, and renders unnecessary the use of metallic wire and chains. Ropes made in the same form have great tensile strength, and being indestructible by fire are of incalculable value for fire escapes.

## BELL'S ASBESTOS.

The goods of this house are of the highest quality only, and no attempt is made to compete with other Manufacturers by the supply of inferior materials at low prices. All orders must be sent direct to the undermentioned depôts, and not through agents or factors.

**BELL'S ASBESTOS BOILER PRESERVATIVE.**—This useful

mixture, by absorbing the free oxygen that is in the water, entirely checks pitting and corrosion. It also disintegrates incrustation so immediately as to prevent its adhering to the plates. Not only is a great economy of fuel effected by keeping boilers clean, but the risk of having the plates burned is thereby obviated. It has been computed that 1-16th inch thick of incrustation causes a waste of 15 per cent. of coal;  $\frac{1}{8}$  inch thick, 60 per cent.; and  $\frac{1}{4}$  inch, 150 per cent. Thus the Preservative avoids the great risks which are inseparable from scaled plates, lengthens the life of a boiler, and covers its own cost a hundredfold by economy of fuel. It is entirely harmless, and has no injurious action on metals. It can be put into the feed tank or boiler, as may be most convenient. Sold in drums and casks bearing the trade mark, without which none is genuine.

**BELL'S PURE ASBESTOS CLOTH.** for protection against the spread

of fire. Iron curtains warp, and in the great emergency of fire will often be immovable. Asbestos cloth, being incorruptible, will remain strong and flexible for an indefinite period, and will stay the progress of a fire and the passage of smoke longer than any other known material. This cloth is also extensively used in Maignen's unequalled water filters, for which a gold medal and diploma of honour were awarded by the Special Commission appointed by Her Majesty's Government to receive the reports of the International Juries at the Fisheries Exhibition. By special arrangement with Mr. Maignen, his filters for houses, factories, and towns are supplied by this firm.

**BELL'S ASBESTOS BLOCK GAS FIRES.**—The Asbestos Block

Gas Fire is formed by placing inside the ordinary grate a hollow block (burner), composed of Asbestos, and perforated. An iron sole-plate, with a single gas burner, is fixed at the bottom of the block. After being lighted a short time, both the block and asbestos fuel throw out intense heat.

**BELL'S ASBESTOS FUEL** for gas fires. This genuine Asbestos Fuel is

composed of the finest hand-picked Asbestos, and its weight is about half that of any other Asbestos fuel.

BELL'S SPECIAL LONDON-MADE ASBESTOS MILL-

**BOARD**, for dry steam joints, made of the best Asbestos fibre, is well-known for its toughness and purity, and is absolutely free from the injurious ingredients frequently used to obtain an appearance of finish, regardless of the real utility of the material. Made in sheets measuring about 40 in. square, from 1-64th in. to 1 in. and  $\frac{1}{2}$  millimetre to 25 millimetres thick. Each sheet bears the Trade Mark.

# The Architect.

## BETWEEN THE PAST AND THE FUTURE.

R. WILLIAM MORRIS, in a thoughtful dissertation which he read last week before the Society for the Protection of Ancient Buildings, lays down the proposition that in this present nineteenth century the artist stands unhappily between two worlds:—one that of the Middle Ages, so far understood if not yet quite clearly; and the other that of certain Ages to Come, not yet understood at all, or to be anticipated even with any serviceable kind of foreknowledge. He puts the case a little more strongly still—and at the same time a little more weakly—in calling upon us to “admit that we are living in a time of barbarism, betwixt two periods of order, the order of the past and the order of the future,” some thinking “that the end of that barbarism is drawing near, and others that it is far distant.”

The idea here indicated is one that may or may not seem to be quite true, according to the light in which it is regarded; but there can be little difference of opinion as to the contrast which the accomplished theorist provokes between the art workmanship of four or five hundred years ago, when looked at learnedly and (as the phrase used to be) “lovingly,” and that of a few hundred years to come, when contemplated with all the faith, hope, and charity of a poetic intellect, whose confidence in the development of the unknown, and perhaps the unknowable, is earnest and sincere.

But surely it need not be part of an attempt to form some impression of this most interesting contrast, that one should previously commit himself to the “admission” which Mr. MORRIS requires, that we are really living in a period of “barbarism.” May we ask his leave to substitute for this ugly word some phrase that shall rather suggest transition or the like, of a creditable, honourable, indeed brilliant kind? Mr. MORRIS, we have little doubt, will say, Certainly not. The barbarous character of this intervening time seems to be, in spite of all, of the essence of the doctrine he would teach. We have fallen from a high estate, and fallen far. Posterity is destined to rise again, and to rise, perhaps, to a higher level than the old; but there is to be no mistake about the fact that we are on low, even very low ground, for the present, and he would probably say that this is the reason why so many of us fail to see so clearly as he does the higher ground of the Mediæval time, and why all of us fail as yet, himself included, to discover, by any intelligible indication, that which in the prophetic days to come is to occupy the lofty table-land of “the order of the future.” Let us at once submit that this condition cannot be accepted by common sense. Every succeeding year's work must satisfy calm observers more and more that this doctrine of “barbarism” is but a rhetorical flourish, and happily there is no need for its serious acceptance as a preliminary to the discussion of Mr. MORRIS's very clever statement of a most important practical question.

This question may be briefly put in plain terms thus:—That the peculiar guild-action (such as we spoke of in another connection last week) of the later Middle Ages was the secret of the success of that period of art-history; that the loss of this vital force is to some extent the cause of the alleged modern incapacity; and that the “order of the future,” when it comes, as come it must, in the shape of some agency yet unknown, will be the basis of a new and true artistic world, to the credit of humanity and its great delight.

Mr. MORRIS sketches with a skilful and earnest hand the broad distinction between the typical slave-artisan or artist of ancient Greece and Rome and the typical guild-master-workman or craftsman of Mediæval Europe, who was not even servant, but free man, doing his work with his own hand at his own pleasure, and thereby earning an easy livelihood with leisure and self-respect. Without disparaging in the least degree the exquisite productions which were accomplished—he thinks under conditions of something like public contempt—in Classic times, he points with enthusiasm to the greater volume of equally excellent work—more excellent work

he would say, because of its all-pervading character—which was produced by independent individualism in his favourite period, of which the fourteenth century was the culmination. From that time to the days in which he himself has, as we are led to suppose, the misfortune to live, the spirit of art he considers to have pined and dwindled away; and this chiefly, if not entirely, by reason of the disastrous development of the antagonistic commercial spirit, with its callous dealers, brokers, traders, employers, its machinists, dividers of labour, managing men, and other vile mechanical persons, whose only business it is to promote the buying and selling of they care not what, in degraded markets they care not where, and the making of “profits” out of “goods”—terms that mean nothing, or at any rate nothing that can be identified with meritorious art; until at length, when England has become “the workshop of the world—often so called with much pride by her patriotic sons,” it would seem as if spinning jennies and the like were the real inhabitants of our tight little island, with “women and children” for their pale and dumb attendants, and the ghost of a craftsman here and there performing the “contemptible task” of an overlooker. No one need care to deny that there is a great deal of truth in this.

But, although there are no doubt many who, with Mr. MORRIS, will stoutly repudiate the qualifying doctrine that this Victorian Age of ours is nevertheless a most grand and glorious era, yet there are many others who are prepared with equal obstinacy, if not with equal ardour, to maintain as much, and to care little, indeed, what may become of the fourteenth century if it cannot take care of itself in consequence. Granted this is a period of mechanical organising, machine-working, listless copying, adulterating, scamping, chaffering, and commercial sophisticating in a thousand ways. But why jump to the conclusion that these conditions are the prime moving forces of the world in art, when such a supposition in any other matter would be so much at variance with the phenomena of human action? “God made man upright” is a dogma which lies at the very root of all the hopes of all good men; that “he hath sought out many inventions” we must confess; but take the good with the bad, the rough with the smooth, and no one who looks below the surface of the matter cares to doubt that the good and the smooth predominate in one way or another everywhere and in everything; and in art it would be idle to pretend to think that this is not the rule, and the only possible rule. Are all the Greek remains, to say nothing of the Roman, equally good art? The Mediæval remains, also, if looked at with ordinary common sense, is there not a large proportion of them that are of very inferior merit, while only a small proportion are of high excellence? So also in our own times, whatever may be the prejudicial effect of various modern conditions, is it not the plain, palpable, sober fact that there is a large amount of admirable art-work produced all over Europe every day—and a fair amount, indeed, of more than admirable work, which, when sanctified by time, will take its place in the collections and museums of the future with all honour? Why pick out the failures alone and ignore the successes, in order to make a show of “barbarism”?

Mr. MORRIS's argument, again, excellent as it is in its suggestiveness, seems to be based throughout upon a postulate which certainly requires consideration at the hands of scientific thinkers before it is so blindly accepted as a certain school of enthusiasts constantly demand. This may be called the doctrine of pure individualism. A work of art, to be worthy of the name, ought to be, upon this principle, the whole work of a single worker. This condition is supposed to elevate the production to the true rank of craftsmanship, and to separate it from the mass of inferior “goods” which is produced by an utter confusion of workers, and even perhaps by abhorrent machinery. It is as if there were three degrees of merit in the beautiful: that of nature, that of man, and that of mechanism—the first mystery, the second art, the third—but who, being pressed to attach to this in soberness a designation of derision, such as it is easy enough to choose from amongst the many phrases of flimsy rhetoric and foolish ecstasy, will venture so far?

At any rate, if we keep to the question of individualism, there is this at least to be said, that, if every craftsman of the fourteenth century were as jealous of his own merit as the admirers of the authenticity of his work in the nineteenth century are, the condition of the guilds, as regards personal conceit and priggishness, must have been intolerable; a state

of things of which we have no evidence in the records or the remains, even if we have not pretty good evidence of the very contrary. The fact seems to be that the worship of pure individualism in art, which we are accustomed to be called upon to regard as a first principle of simple intelligence, is but an incident peculiar to our own modern times, part of our system of commercial authenticity, and, even in its more intellectual aspect, nothing more than part of that development of "the Revival of Arts and Letters," "the Renaissance," which we are sometimes inclined to disparage and repudiate nowadays, but whose children we nevertheless still are, and cannot help it.

To take an illustration from architecture, the reader will perhaps acknowledge that this, when at its best, is an art of undeniable refinement, majesty, and glorious power. And yet this is the one art in which the artist cannot possibly do the work with his own hands. In his shrewd, paradoxical way, Sir EDMUND BECKETT seized upon this fact not long ago, when in a merry mood, and by an easy syllogism deduced from it the sarcastic conclusion that an architect is not an artist at all! What would Mr. MORRIS say? But suppose some one of our great architects, instead of trumpeting abroad his artistic individuality, were to disclaim it altogether on principle, saying, "Here is art, no matter whose; hundreds of workers have delighted in it; and their fit reward is this—let thousands of observers have a like delight; to ask their names is idle, to answer profane!" We are not afraid to think seriously that this was very much the spirit of "the order of the past."

Perhaps "the order of the future" is to be a state of things in which a work of the beautiful will be judged of by its own merits, and the name of the men, and of the machines, that made it, alike relegated to oblivion. Possibly, after all, our worship of names is but an easy way of cataloguing merits which we cannot recognise, and of appraising "goods" which we do not understand.

## STUDIOS IN ROME.—BARON VON LEMBACH'S.

[BY A CORRESPONDENT.]

AMONGST the remarkable studios of Rome, that of the Bavarian painter, F. VON LEMBACH, must certainly be enumerated. His fame as a portrait painter is European. His studio may be considered as a portrait gallery of some of the most notable personages of the time, some record being retained either in drawing or otherwise of the majority of the portraits he has taken. His studio, adjoining that of the celebrated private collection of the Prince BORGHESE and under the same roof, may be visited together with that assemblage of masterpieces, to which his works offer a not altogether unworthy pendant, exemplifying, as they do, so much of the influence of the older painters in modern forms.

His works consist entirely of portraits, all of them executed with manly grasp and vigour, whether his subjects be taken from the drawing-room or the senate. His mode of working is very interesting. Previously to painting he usually makes a preparatory study in coloured crayons, touched upon with distemper. This is done of a size more or less approximating to that of life, on a sheet of brown-grey cardboard of a certain quality or texture. Sometimes these preparatory studies are thinly painted in oil on the same material. Some of them are very striking, from their forcible drawing and generally expressive treatment. Of these, many are to be seen in his studio. It would seem as if the painter in the first instance strove to seize the distinctive character and broad effect of the face or figure to be painted, and then to bring into it the artistic qualities of richness of colour and pictorial values. His first studies are made with considerable rapidity and great mastership of handling. The eyes form a most prominent feature, and are usually seized upon as the prime indicator of the face. Some of his portraits glow with colour, reminding one of the master-painters in this respect—REMBRANDT, RUBENS, and the Venetian school. Others, again, are executed with high regard to the modelling, or rather to the expressive lines of the face, as of HOLBEIN. All are noticeable for some artistic quality, though they do not all make their appeal in the same direction.

To enter into a more special examination of these works

in passing round the studio, we are first struck with a fine portrait of STROSSMEIER, the Archbishop of Agram. It is thinly painted, gray in tone, and full of power and intelligence. Of WAGNER we have several portraits, all of them more or less characteristic. One of these represents the poet-musician seated, full-face view, smooth in texture and transparent in quality, reminding us of some of the finer examples of the Dutch school. There are two very spirited portraits of BISMARCK. One gives him seated with his hat on, which covers an eagle-like face in its piercing intensity of gaze, as if the eye had indeed the energy of life behind it. In the other he is represented standing bare-headed, the full modelling of the face coming out in strong relief. Both of the portraits reveal the energetic statesman, the inflexible will, with a stern and indomitable force of character. The portrait of Dr. DÖLLINGER is monumental in its fine and expressive treatment, and might very well find a place in a gallery of worthies of the time. In the portrait of the CROWN PRINCE of PRUSSIA we have a dignified and majestic half-length figure, rendered in rich, low-toned colours that bring the work of TINTORET to mind. A very charming picture, with some tender passages of colour, is a portrait of a German lady carrying a baby with a doll. This has much of the broad rendering that belongs to our English last century school of portraiture, reminding one of REYNOLDS in his richer moods. There are two portraits of GLADSTONE: one severe in modelling, thorough in drawing, thoughtful and earnest in expression, as though it bore the impress of the cares and harassment of statesmanship of many years. The other is more reflective than active in expression: it might be interpreted as representing the man rather than the statesman. The two pictures may thus be said to form companion portraits. Another characteristic likeness is that of the Prince TEANO of Sermoneta. With a face somewhat long and spare in feature, it expresses great nervous energy, an expression to which the strongly-drawn hand placed upon the breast contributes. That of the Prince BORGHESE is a fine, well-grasped portrait, the grey hair and beard being specially well rendered. The Marchesa LAVAGGI, represented in evening dress, the head turned over the shoulder, is large and serious in treatment, full toned in colour, but somewhat over-refined in drawing. Not less distinguished is the full-length likeness of the PRINCIPESSA DEL DRAGO, granddaughter of the Queen of SPAIN. In the portrait of the sister of the artist, an early painting, we have a work which obviously has been done under the direct influence of REMBRANDT, rich and brown, but deficient in the reposeful neutrals of his great prototype. Of Baron LIPHARDT we have several portraits, the painter evidently having been fascinated by a certain severity of line and seriousness of character which distinguish the face. They are mostly in profile; all excellent both in modelling and in colour. He is represented as wearing a black skull-cap, with much of the scholarlike aspect and thoughtfulness which is impressed upon the personalities of the English divines of the seventeenth century. A Hungarian lady is given in a dramatic attitude with one arm raised to her breast. This is at once dignified in pose and impressive in its powerful execution. Perhaps one of the sweetest and most sympathetic of Baron VON LEMBACH'S portraits of ladies is that of Madame ANTONINA DIEZ, the wife of the Uruguay Minister in Rome. A fillet is worn round the head, which is natural, sweet, and unaffected.

Amongst the drawings on card in pastel and distemper we have MOLTKE in profile, severe and lifelike in character; the Marchesa DEL GRILLO, daughter of Madame RISTORI, the well-known actress, a well-turned profile, excellent in likeness; and another charming profile, earnest and lively in expression, of the young Princess MASSIMO. There is also a happy drawing of the head of a girl of ten or eleven, with hair streaming on each side of the face against a blue sky background, which might have been from the hand of one of the early Umbrian masters.

In thus passing through the studio of this painter one cannot fail to be struck with the evidences of a high artistic power, which, nevertheless, is not equally distributed throughout his works. They lack the impress of a distinct personal character. One is continually reminded of some older type of greatness which they recall; always good and noble, but not absolutely the artist's own. He has *discovered* nothing. His work does not suggest any new point of view, any fresh mode of interpreting or regarding the facts of nature, qualities which

always distinguish that of the first masters. Again, there is a want of clearness and purity both of tone and tint in many of his pictures. There is a tendency to heaviness in some of them. In spite of their facility of treatment they lack spontaneity and freshness. One misses in them the wholesome frankness and sweetness of the English school of REYNOLDS and GAINSBOROUGH, and even of the lesser masters of the same or a later period; as in the works of Sir THOMAS LAWRENCE, for example. As has been said, the painter aims mainly at giving a decided character to his faces, and in this he generally succeeds. Whatever their shortcomings, however, there is no question as to their merits, nor to the fact that they may be studied with pleasure and profit.

### AN ARCHITECT'S SKETCH-BOOK.\*

A NEW volume of architectural sketches can suggest thoughts unlike those which arise on the appearance of the majority of books. It is sometimes difficult to speculate what kind of men and women are the writers who are described in the advertisements as "new authors," but it may be safely assumed that an architectural sketch-book has been produced by a young and most probably by a happy man. He may have returned from his first Continental trip after seeing everything with a delight which unhappily does not accompany subsequent visits. Seen on a summer's day, a town in Belgium or France cannot fail to be pleasing; but it appears enchanted ground when one comes to it in youth from a drawing-board in a back room in a dull English town. The power of representing things on paper assumes a new value on finding that it enables us to perpetuate our pleasure. The simplest sketch acquires some of the glamour of the place, and blacklead lines in a mysterious way recall not only colour but everything that gave life to the scene. We feel that we have discovered the treasure, and, oblivious of what has been done by men who were more clever than ourselves, we resolve to reveal the glories of the town or of the building to the untravelled. So the sketches are produced. After a time the value of them is diminished in the author's eyes, they seem hardly worth the expenditure of so much enthusiasm, and it would be difficult to persuade him to put his name to a second volume. Poems, histories, tragedies, novels, and treatises on the differential calculus may come from men of mature age, but not books of sketches of buildings.

We were not surprised to find a commonplace church tower in Mr. THORP's book, accompanied by a description which said that the sketch was made during a summer holiday, or that "the day when it was visited was gloriously fine, and the old grey tower, with its corbelled-out belfry stage, backed by the spreading branches of some ancient Scotch firs, their ruddy stems visible through the deep green foliage, stood out clear and distinct against a sky of the most intense blue." It is generally under those circumstances that architectural sketches are made. In another place we read that at Woodsome "an air of quiet and dignified repose seems to pervade the very atmosphere." The little slate spirelets in Bruges are said to have a charm that is beyond description, "and nothing can excel them for subtle effects of light and shade and wealth of artistic colour;" a fountain in a market-place recalls the "merry groups of children who resort hither, not merely to draw the daily supply of water, but also to splash one another with the sparkling and transparent liquid." An old timber house is said to be "helped considerably by the garden in the foreground, which at the time the sketch was made was a perfect blaze of colour." If the trees were omitted we could almost divine that the sketches were a summer's task by a man who has an artist's sensitiveness to whatever is beautiful in out-of-doors life. To appreciate a book of this kind properly one ought, perhaps, to have accompanied the author, and to have enjoyed the scenes as he did. Things of beauty in an architectural sense are not always equally joyful to all men, and some of the subscribers may feel compunctious visitings of conscience on remembering that, in days when there was no reverence for Queen Anne, they saw a few at least of the buildings drawn by Mr. THORP without thinking there was anything remarkable about them, unless it was their lawlessness.

The "Home" sketches are selected from Yorkshire buildings which are accessible from Leeds, and have been made in holiday leisure. There are accordingly associations about them which must have enhanced their value in the artist's eyes; but if judged simply as examples of architecture, it must be said that in general design and in details they are inferior to the foreign buildings which are represented in the volume. Calverly Old Hall (which is supposed to have been the scene of the events of the Elizabethan play "A Yorkshire Tragedy"), Woodsome Hall (with its terrace and balustrade), and Cawood Castle are the best of the secular buildings. There are details which have undoubted interest. One is the stone recess or "sideboard" in Harewood Castle, which resembles an Easter sepulchre, and must have been as grimly suggestive in a dining-hall as a mummy at an Egyptian feast. A second good bit is the window recess in Hawksworth Hall, in which the carved work is not superabundant in quantity. The oak staircase in Woodsome Hall shows newels and balusters which are in good proportion, and the newels are not excessively large. One does not wish to vilify native work, but all that can be said in favour of some of the subjects is that they were produced in the seventeenth or eighteenth century; to many people that will be sufficient to give them fascination.

The Belgian buildings are the work of a different class of men, and there are many which do not depend on local associations for their interest. A good many come from Bruges, that picturesque old city which has suffered a reverse of fortune, but somehow, amidst its quietness, impresses one with the feeling that it is to be prosperous again, as it deserves to be, if it were only on account of its patronage of the arts. Every man who has been there has his own special favourites, and two would hardly agree in making a selection. But Mr. THORP has done very well in what he has given. We have the beautiful baptistery of Notre Dame, which looks like the design of a metal-worker, the series of windows which are combined into one big window at the Mont de Piété, the Belfry of the Halles (very carefully drawn), and a great many details of work in brick, wood, metal and slate. Next come the extracts from Ghent, the city of which CHARLES V. said that he could put the whole of Paris within its walls. Whatever may have been the relation between the emperor's Gand, and the Paris of the sixteenth century, the modern Ghent, although one of the most scenic of cities, will not admit of a comparison with the French capital. The houses appear to have been intended for a wealthier race than their present possessors. Mr. THORP gives the Maison des Bateliers, in which the windows are better than the gable, an old house near the Hôtel de Ville, the house on the Marche du Vendredi which is said to have been occupied by the terrible Duke of ALBA. The last is now a second-hand clothes shop. A small sketch is given of the fine tower of St. Nicholas, the oldest church in Ghent. It was on this tower that PHILIP VAN ARTEVELDE, according to Sir HENRY TAYLOR, used to find occasional repose in the time of the war between the White Hoods and the Earl of FLANDERS, and some of the scenes in the dramatic romance of the poet are laid in this church. Some very good sketches of houses have been supplied by Ypres, as well as the tower of St. Martin's Church, erected in 1254, and which happily "remains in its original condition untouched by the hands of the restorer."

Mr. THORP's book should have an interest for bibliographers, if it were only on account of the pains he has taken to illustrate the house in Antwerp which belonged to CHRISTOPHE PLANTIN, the great printer, who was the rival of ALDUS in the sixteenth century. The family were proud of their printing office, and it existed for more than two centuries. The buildings date, according to Mr. THORP, mainly from the beginning of the sixteenth century, and the visitor is impressed by their repose on entering:—

The general effect of the court with its arcades sheltered from the glare of the sun, above which, framed in elaborate cartouche work, appear busts of the worthy owners, its mullioned windows glazed in leaded patterns, with here and there a quaint dormer rising above the roof line, is highly picturesque; the effect being, no doubt, considerably enhanced by the luxuriant growth of an ancient vine which festoons itself against the walls, the greenery contrasting admirably with the mellow deep red tones of the brick-work background.

The drawings of the Plantin Museum consist of a view in the court, a part of the staircase, a chimneypiece, and plates of details of the woodwork. The design of the work is of a high

\* "An Architect's Sketch-book at Home and Abroad." By William H. Thorp, A.R.I.B.A. Published by R. Jackson, Leeds, and B. T. Batsford, London.

character, and it is evident the owners were as careful in selecting their builders as their typefounders. It is the best of all the mansions represented by Mr. THORP. Some other sketches have been derived from Antwerp. Malines is represented by the picturesque Couvent des Carolites, of which the upper part is better than the lower; and Namur by a sketch of the interior of St. Loup, which is less finished than others in the book. Two views are given of Dinant, a town which of late years has become a centre of attraction to artists. Treves has gained importance in connection with the new views on the relation between Western architecture and Rome, but Mr. THORP's sketches are mainly of domestic buildings. It is a town which has yet to be thoroughly explored. There are some very good sketches from Berncastel and Cochem. The latter appears to be well worth a visit during holiday tours. A view is given, among other buildings, of the Schloss Elz, near Moselkern, and if the interior is as good as the exterior it deserves to be amply illustrated.

Mr. THORP's sketch-book appears at an opportune time, when the holiday programmes are being arranged. The author takes delight in picturesque architecture, and is quick in his recognition of the good points of a building. In his book there are many drawings which everyone must admire. The architects of the old buildings represented by Mr. THORP are forgotten; but there is no doubt that they were artists, and it would be strange if, from such a collection of their works, inspiration cannot be drawn without much difficulty.

### EXHIBITION OF SCOTTISH PORTRAITS.

**A**N exhibition of Scottish portraits was opened in the Royal Scottish Academy Galleries on Saturday last. Among the 570 canvases for which space has been found, a good many will be recognised as having appeared in recent loan exhibitions. The difficult task of hanging has been judiciously accomplished by Mr. Gourlay Steell, R.S.A., Curator of the National Gallery.

On entering the rooms, says the *Scotsman*, the visitor will find himself among a quaint and interesting company of royal, noble, and ecclesiastical personages, who in their day played a somewhat conspicuous part in Scottish affairs. Among the artists represented here are Jamesone, Janssen, More, Holbein, and Mytens; but a large proportion of the portraits, and some of these by no means the least noteworthy, are of unknown authorship. Such are the likenesses in one frame of James V. and Mary of Guise, a work which has been described by Miss Strickland, and is further known through engraving. This most desirable contribution has been obtained from the Marquis of Hartington, who also lends a full-length of James V. as a child, and two portraits of Arabella Stuart, one of which represents that ill-fated lady as a little girl holding a doll. James VI. appears on several canvasses, including a half-length by Janssen and a full-length ascribed to Jamesone, most of which agree tolerably well in their rendering of the sapient monarch's shrewd, if by no means distinguished, lineaments. Of James's consort, Anne of Denmark, there are two whole lengths, one credited to Jamesone, giving her a refined complexion, and an extraordinary redundancy of hoop; the other, by Mytens, less extravagant in costume, but not at all so refined in colour. Of Mary Stuart there are several likenesses, of which one by Zuccherro, and that belonging to Trinity College, Cambridge, though faded in colour, have considerable interest of expressions, while a cabinet head, attributed to More, suggests more than either of the Queen's traditional beauty. Fine examples of More are to be found in cabinet half-lengths of the Abbot of Newbattle and his wife; and to the same hand some will be inclined to attribute a masterly portrait of the second Earl of Arran, to which is appended the name of Zuccherro. Holbein's solid and searching realism is illustrated in heads of Margaret Tudor and James IV.; and a charming example of Van Somer presents itself in the softly-modelled and delicately-coloured face of a Countess of Ancrum. Of the numerous portraits assigned to Jamesone, one of the most undoubtedly genuine is probably the half-length of the first Marchioness of Argyll. A family group, showing the artist with his wife and child, is understood to be a copy. Other examples, while probably authentic, bear manifest traces of retouching; and there are some which will hardly be accepted by experts as the work of the "Scottish Vandyke."

Passing to the second room, one finds a considerable space occupied with specimens of Lely and De Medina. The former is seen, perhaps, to most advantage in a refined portrait of Archbishop Sharp and a vivacious half-length of David Leslie, commander of the Scots forces in the Civil War. There is no superfluity of refinement in his exuberant three-quarter length of the Duchess of Lauderdale, and still less in that of the Duke who gained unenviable notoriety as the persecutor of Scottish Presbyterianism. Of De Medina's work there are a portrait of the first Earl Stair, who was Secretary of State, under William III., when

the massacre of Glencoe was ordered, and a delicately-coloured half length of Frances, Countess of Buchan, granddaughter of the author of "Religio Medici." A spirited full-length of Sir James Pringle, in the costume of the Royal Archers, does credit to the art of D. Martin; while that of G. Hamilton makes a favourable impression in his rendering of the beautiful Elizabeth Gunning, wife of two and mother of four dukes, whose portrait by Reynolds will be remembered as a feature of last year's loan collection. A sumptuously costumed whole length of a Marchioness of Lothian displays the courtly elegance of Allan Ramsay, whose manner shows with more telling effect in his seated portrait of the second Duke of Argyll, in richly ermined scarlet robe. A half-length of Charles I., attributed to Vandyck, can only be accepted as that artist's work on the assumption that the distortion of the features is the result of clumsy repainting. Other examples of the great Fleming are the first Lord and Lady Belhaven in one frame, the second Duke of Hamilton, and those three views of the head of Charles I. which the king sent to Rome with a view to the execution of a bust, and afterwards presented to Lord Strafford. In a bust portrait by D. Patton of General Thomas Dalrymple, the suppressor of the Pentland rising wears a somewhat rough and unkempt look in his shaggy beard and long white hair. The same figure, with long hair, but without the beard, appears in capitol painted armour in a three-quarter length by C. Jansson. A curious design by Delacour represents Sir Stuart Thriepand in the act of being warned by a cherub as to how he should escape from Culloden; and there are two interesting portrait groups by D. Allan—one of the Mar family, of the middle of last century, in the grounds of Alloa House, the other of the Cathcarts, assembled about a tent on the field that witnessed the first cricket match ever played in Scotland.

On entering the great room, attention is at once arrested by the familiar hand of Raeburn, represented by such well-known masterpieces as the delightfully-posed and charmingly life-like Mrs. Bell; the vigorous Nathaniel Spens, drawing his bow in the costume of a Royal Archer; the dignified full-length of Lord Frederick Campbell, robed as Lord Clerk Register; the effectively-lighted portrait of Roland of Gask, the original of Scott's Pleydell; the stately figure of Viscount Melville; the fine likeness of Sir Walter Scott, seated with his dogs by ruined tower; and the broadly characteristic presentments of the Rev. Sir H. W. Moncreiff, Dr. Hutton, Adam Ferguson, Henry Mackenzie, Dugald Stewart, and Archibald Constable. In a goodly representation of Reynolds there is to be noted as of special significance the animated portrait of Dr. William Hunter in the act of lecturing. Very beautiful in colour is a bust of Lady Minto; full of charm alike in figure and landscape background is the full length of a Duchess of Buccleuch, though here the flesh colour shows just a little the effect of that decay of the glazings which in the group of the Ladies Montague has gone the length of compromising the modelling and reducing the flesh to an unnatural paleness. This process of fading is also observable in a half length of the Third Duke of Buccleuch; but sound enough, to all appearance, in colour, though in a rather dingy condition, is a head which one readily recognises as a thoroughly credible likeness of James Boswell. To Sir Joshua has been attributed the three-quarter length of a Duchess of Gordon, which, in the opinion of competent judges, ought rather to be assigned to Romney, and which certainly seems to bear that painter's sign-manual in the piquant pose of the figure and the dainty painting of the simple white dress. Noteworthy for the solid modelling of the head is a bust portrait by Romney of Macpherson, the redactor of Ossian, though it is difficult to identify the likeness with Reynolds's representation of the same person, which hangs close by. Among several fine examples of Sir Thomas Lawrence, special notice is due to a life-like head of the witty Dr. Moore, and a half-length of his heroic son, presenting among other merits a notably artistic treatment of the British military uniform. Gainsborough is represented by a refined head of Lord Chancellor Erskine, and one of George IV. as Prince of Wales, in which he hardly rises above the level of the fashionable court painter. Sir J. Watson Gordon is seen at his very best in a half-length of the late Principal Lee, highly noteworthy for the use made of greys in the modelling of the features; and there are also from his hand, in this room, excellent portraits of Sir James Hall and Sir T. M. Brisbane. Of the specimens of Geddes, the most interesting, artistically, is the full-length of Patrick Brydone reclining on a sofa, which has been reproduced by Ward in an effective mezzotint. Besides the portrait by Raeburn above referred to, there are more or less satisfactory renderings of Sir Walter Scott by J. Graham Gilbert, C. R. Leslie, Sir J. Watson Gordon, and Colvin Smith; while the novelist is seen in the midst of his family in the picture by Sir David Wilkie, well known through engraving, and again appears with two of his dogs in the sketch for Landseer's painting. Of Chalmers, again, there are several portraits, the best being that executed when the great preacher was well advanced in life by Thomas Duncan; to whose pencil is also due a cabinet full-length of John Wilson in sporting costume.

In the fourth room Sir J. Watson Gordon again figures largely with, among other portraits, the dignified and attractively-coloured

full-length of Lord President Hope in judicial robes; and the fine three-quarter lengths of Lord Rutherford, Lord Chancellor Campbell, and Principal James Forbes. Raeburn is also represented here by his likenesses of Home, Horner, and Jeffery; and Hoppner by a charming seated portrait of a lady in white, with background of admirably-handled landscape. Then there are a cold-toned but eminently-gentlemanlike portrait of the late Duke of Buccleuch, by Sir F. Grant, and a full-length of a member of the Buccleuch family, by Sir D. Wilkie; on whom is also fathered a rather feminine-looking likeness of the poet Campbell. The best manner of the late Sir D. Macnee may be seen in a portrait of George Combe; the less satisfactory style of his later years in an animated portrait of Robert Carruthers; by way of pendant to which is hung the vigorous three-quarter length, by N. Macbeth, of Carruthers' friend and brother journalist, Alexander Russel. A fine portrait of the Rev. Dr. Inglis, father of the present Lord President of the Court of Session, testifies to the skill of J. Syme; and in the hands of W. Dyce the head of Edward Irving, with its piercing eyes and long black hair parted down the middle, has certainly lost nothing of the weird fascination that helped to sway excited crowds. Scattered through this room are numerous portraits of artists, of which may be mentioned the fine head of Skirving by Raeburn, Sir F. Grant by J. P. Knight, Sir J. Watson Gordon by himself, a masterly *ipse pinxit* of Philip, and from the same hand heads of the late W. Brodie and James Cassie; the late Sir D. Macnee as a young man, by T. Duncan, and a bust likeness of the late D. O. Hill, which is perhaps one of the best bits of portraiture ever done by R. Herdman. Other works here from Mr. Herdman's pencil are a capital half-length of the late David Laing, a good likeness of the late Dr. Hanna, and an expressive head of Thomas Carlyle, whose portrait by Whistler, recently exhibited at the Salon, will also form a feature of the collection.

The fifth room contains several excellent examples of Allan Ramsay, including a head of Lord Elchies, particularly effective in colour; as also a number of portraits by Lely and De Medina. A three-quarter length of the first Earl of Rosslyn, attributed to Raeburn, looks as if the face had been painted by that artist, and the rest of the work by some other skilful hand; and near by may be seen the curious picture by Hogarth, full of character, if not without a dash of caricature, in which Lord Lovat appears, as is understood, in the act of counting off upon his fingers the number of days to elapse before his execution. On a screen in this room are a number of excellent portraits in crayons; and here too, as elsewhere throughout the rooms, is set out an interesting collection of busts; while in glazed cases are disposed engravings, miniatures, a fine set of Tassie medallions, and casts of Scottish portrait medals lent by the British Museum.

## THE ART LIBRARY, SOUTH KENSINGTON.

THE following is the report of Mr. R. H. Soden Smith on the acquisitions to the Art Library during the past year:—

The number of volumes and pamphlets acquired has been 2,294. Among these may be named two of the rare Venetian lace pattern-books; the earlier, entitled "Bellezze de Recami et Desegni," is extremely uncommon; it was brought out at Venice in 1558, and contains 20 pages of designs, many of great elegance, all in perfect condition, and including upwards of 100 patterns for lace borders; the other is also rare, "La Vera Perfectione del disegno de varie sorti di ricami," &c., by Giovanni Ostaus, Venice, 1591; a rare work of Du Cerceau, containing elaborate engravings of ornament of the date 1594—a beautiful little volume in its original stamped vellum cover; a curious book containing receipts for dyeing and colouring, &c., sm. 4to., 1605, translated from the Dutch by Leonard Maskall, the author of "A Booke of Fishing with Hooke and Line," &c.; a fine series of the engraved works of Le Pautre, about 1,000 prints collected in 7 folio volumes (these volumes formed part of the Townley Library, and represent very fully the various works of the great French decorative artist); Turner and Girtin's "River Scenery," 1823-30; two early publications by David Cox, now become rare, his "Lessons in Water Colours," 1823, and the "Young Artist's Companion," 1825; several works illustrating costume, as "Lami, Bal costumé," fol., 1829; "Petit Courier des Dames," 43 vols., 1835-57; "Costume du Theatre français," 5 vols. 4to.;—Gerhard, Griechische Vasenbilder, 4 vols., 4to., 1839-58; "Canina, Antica Etruria Marittima," 2 vols., fol. 1846-51; Stirling-Maxwell, "The Victories of the Emperor Charles V.," designed by Heemskerck in 1555, portraits, prints, &c., added, fol. 1870; a few works on natural history selected for their successful illustrations, as the "Game Birds of the United States," fol. 1878, and the "Game Fishes of the United States, 1879"; various publications having for their object the more complete illustration of the works of the great masters, as Amand-Durand's "Eaux-Fortes et Gravures des Maitres anciens, 1870-72; Unger, "Musée National d'Amsterdam."

Some additions have been made to the class of illustrations of early printing and book ornament. The increasing zeal of col-

lectors in this direction both at home and abroad renders it difficult now to acquire specimens except at prices practically prohibitive for the Art Library. Among the acquisitions may be mentioned an early black letter "Rosario Gaudioso," imperfect, but with numerous wood engravings and ornamental borders to each page; Ambrosio Montesino "Epistolae y euangelios," containing wood engravings and ornamental initial letters, folio, printed at Toledo, 1512. (Toledo printing of that date is not common.) "Missale Ord. Sanc. Benedicti" (Germany), very fine black letter type, with borders and initial letters rubricated, printed at Hagenau in 1518; this is also a fine example of stamped leather binding of the period. "Missale Romanorum," folio, printed in red and black, with full-page engravings and elaborate initial letters, Antwerp, Plantin Press, 1572.

The collection of bookbindings has received some additions; the observation previously made respecting early printing applies, however, with even more force to the attempt to collect bookbindings—the prices now obtained for rare or fine examples would have been deemed incredible a few years ago. A curious piece of early Flemish binding of the fifteenth century has been acquired, in leather, moulded with figures in relief of St. John the Baptist under a Gothic canopy (inserted in a large folio modern cover with brass corners and clasps); a specimen of Nuremberg binding of the end of the fifteenth century, folio, enriched with stamped diaper and other ornament, with original brass corners, centre ornament, and clasps; a curious sixteenth-century binding in green velvet, German ("Vita Phil. Melanchthonis"), stamped on one cover with figure of Luther, and having inserted on the other a stamped and coloured portrait-figure on vellum of Melancthon; various examples of stamped hogskin, of Flemish and German origin, some initialed with the names of the designers, and several dated. The admirable skill shown in these bindings is at length beginning to be widely appreciated, but fortunately the Art Library has already secured a fair representation of this class of art workmanship. There may also be mentioned a small leather binding, Antwerp, 1558, in stamped calf, with graceful border ornament of foliage with birds; another of similar style has also been secured, elegant in design, but not in as good condition as could be desired; a specimen of Venetian stamped vellum of very good design, of the date 1570; another Venetian example, but in dark crimson morocco, about 1583, very richly gilt with foliated arabesques; a French crimson morocco binding, tooled and gilt with royal crown and collar of St. Esprit, dating from 1661 (this came from the Townley Library); a southern German binding in crimson morocco, tooled, of the first half of the eighteenth century; two English examples in red morocco, much gilt, dating respectively from 1714 to 1744, the latter inlaid with white leather richly tooled.

It has been found necessary to purchase duplicates of a considerable number of works much used in the reading-room or required for circulation to provincial schools; also in some cases to supply the place of copies practically worn out by almost daily use during about twenty years; many more are still needed. Among the duplicate copies may be mentioned:—Pistolesi, "Il Vaticano," 8 vols., fol., Rome, 1829-38; "Sir Joshua Reynolds's Engraved Works," 3 vols., fol., 1833; Nash's "Mansions of England," 4 vols. (original issue); Britton's "Cathedral Antiquities," 5 vols., 1836; Colling's "Gothic Ornament," 4to., 1848; Pfnor, "Palais de Fontainebleau," 2 vols., 1863; Meyrick's "Ancient Armour," 3 vols., 4to., 1842; "Les Emaux de Petitot," 2 vols., 1862-64; also a series of the "Gazette des Beaux-Arts," from 1869.

The number of original drawings acquired has been 2,822, of these 195 have been presented.

Among the latter may be mentioned a series of 120 pen sketches in Spain, by the late Sir M. Digby Wyatt, presented by Lady Wyatt; chalk studies of drapery, by Sir F. Leighton, P.R.A., presented by himself; an Italian coloured drawing of an altar-piece from the original, by Luca della Robbia, presented by Lady Bouchier. Of the drawings purchased may be mentioned a most interesting series of 248 original illustrations, folio size, of Hindoo costume, by Balthazar Solvyns, a Flemish artist who brought out in Calcutta in 1799 an important work on the native costume in a series of etchings, by himself; these drawings, executed about 1798, are the originals which he made for his subsequently-published plates. A set of fifteen large and elaborate illustrations of the decorative details of the "Taje Mahal," Agra, giving full-size examples of the beautiful inlay work; a valuable collection of 140 drawings of fruit and flowers, beautifully coloured, which were executed for John, Count of Nassau, by John Walter about 1654, from plants growing in the gardens of the Count's palace in the Duchy of Nassau. These drawings were acquired by the Earl of Bute, the minister of King George III., and bound for him in two handsome volumes; on the dispersion of his library they were obtained for Mr. Beckford, and thus came to the Hamilton Palace Collection, from which they were bought for the Art Library. A set of eighty-two drawings of details of Classical architecture made by Robert Adam about 1750; six very interesting drapery sketches in oil, by Hogarth; upwards of thirty original studies, by Flaxman; academical and other studies, by Stothard, West, &c.; pencil drawings by Prout; many studies of sky, trees, and details of foliage by Varley and others; a collection of designs

for various decorative objects, also for architectural ornament by various Italian and other artists; a series of drawings of ancient armour and weapons by the late Lieut.-Colonel C. Hamilton Smith; a very highly-finished drawing on a large scale, in colours heightened with gold, of a twelfth-century altar frontal in the Wallraf-Richartz Museum, Cologne.

The collection of early illuminations has received the important addition of 355 pieces, chiefly initial letters from MSS. of the thirteenth to fifteenth centuries, including examples of the Italian, French, German and Flemish schools of missal painting.

The number of engravings, etchings and woodcuts added to the collection has been large, in all 18,107; of those presented may be mentioned a series of eighty etchings by F. Goya, published 1799; and a collection of 262 engravings issued by the Calcografía Nacional, Madrid. Among the purchases are many classed series of architectural objects and decorative details, as towers and spires, chimneypieces, staircases, doorways, pulpits, &c., besides croziers, chalices, vases, book-titles, and other series which are being completed for the special use of students of ornamental art; a few additions have been made to the collection of the works of the "Little Masters" of the early German school; also to the woodcut book ornament of the fifteenth and sixteenth centuries; a large and curious collection of upwards of 1,000 title pages, frontispieces, colophons and other book ornament, in six folio guard books, has been acquired, also another set of such subjects numbering more than 300, together with about 130 printers' devices, head and tail pieces, &c., besides large additions to the collections of woodcut and other initial letters; the series of book illustrations of the last century has been added to as well as that of portraits of artists.

The number of photographs added to the collection has been 1559. Among these, which for the most part are printed by processes believed to be permanent, may be mentioned a set of illustrations presented by M. de Champeaux, of decorative furniture exhibited by the "Union Centrale des Arts décoratifs" in Paris; a collection representing objects of antique art in the Royal Museum at Naples; several important series of autotypes illustrating the contents of the great European collections; among these last are 400 representing the paintings in the Prado Museum, Madrid, and a small series of the paintings in the Academy of San Fernando; upwards of 300 historical portraits exhibited at the Trocadero, Paris; the collection as far as yet issued of the paintings in the galleries of the Hermitage, St. Petersburg; also large illustrations of the decorative designs for the Opera House, Paris; the society for photographing such remains of Old London as still are permitted to exist has issued a few photographs, of which two sets have been acquired.

### THE FOUNTAINE SALE.

THE following statement respecting the objects purchased by the syndicate at the Fountaine sale has been written by Mr. J. C. Robinson:—An estimate was in the first instance made by Mr. Franks and myself of the probable price which each of the chosen specimens might be expected to realise, and the result of the sale was, we think, not less remarkable than satisfactory. While, as was sure to be the case, some of the objects, the greater number in fact, were sold for less than our estimated prices, others considerably exceeded them; but, taking one lot with another, the aggregate amount paid for the entire series was, on a gross sum of nearly 10,000*l.*, about 200*l.* under our estimate.

Nearly thirty years ago Mr. Franks and myself were commissioned by the Government of the day to select and purchase works of art at the sale of the Bernal collection for the respective museums with which we were officially connected. The late Mr. Andrew Fountaine also made many purchases at the Bernal sale to add to his ancestral collections. We were both intimately acquainted with him, and although he was an enthusiastic collector, he generously stood aside and waived his own pretensions whenever any particular specimen was especially wanted for the nation. This was more especially the case in the ceramic section. For this reason, in particular, Mr. Fountaine did not obtain the real gems of the Bernal sale; these, for the most part, unquestionably went to South Kensington and the British Museums. But the specimens bought at the Bernal sale by Mr. Fountaine have again been brought to the hammer at Messrs. Christie's, and, on the average, they have realised at least ten times the sums they cost him. Shortly after the Bernal sale, in 1856, came the purchase of the Soulages collection for South Kensington, effected in the first instance by a syndicate, exactly as has now been done at the Fountaine sale. Curiously enough the guarantee fund raised on that occasion amounted to about the sum now contributed—about 24,000*l.*—while the cost of the collection was about 11,000*l.* There was endless trouble and demur before the Soulages collection was finally taken to by the nation, but it was one of the most splendid and successful acquisitions of the kind ever made by any country. I think those who know will bear me out when I say that the Soulages collection would now, as a whole, sell for at least five times the price paid for it, while the objects in certain

sections would attain a far greater rate of advance. Most assuredly a similar result might be counted upon in the future in the case of the objects now under offer to the nation by the Fountaine syndicate. Now for a less satisfactory picture. It is the fact that, with the exception of the objects secured by the syndicate, nearly all the principal specimens in the Fountaine collection, whether bought at the sale by English or foreign agents, were acquired for Continental collectors, and are now practically lost to the country.

The most beautiful and precious work of art in the collection—the ivory horn—has gone to Paris, not to Vienna as at first reported. This coveted work was lent by the syndicate to be dealt with by the authorities of the South Kensington Museum, and it was expected that a vigorous effort would be made in that quarter to secure it. The biddings on the part of the museum ceased, however, at 2,000*l.*, and the real competition was between a spirited Bow Street expert and a wealthy Parisian collector. Had the prize fallen to the former gentleman it would have been his object to resell it at a profit. As it is, it has passed into the most splendid and precious collection of works of decorative art formed in our time. In this unrivalled gathering many of the chief treasures have been year after year gleaned in this country, to which it is now certain none of them will ever again return, for it is understood that the entire collection has just been formally made over as a gift to the museum of the Louvre.

I apprehend that the foregoing facts speak for themselves; one thing they seem to attest is that whereas only a few years ago we led the way as a nation in the matter of industrial art collections, we have now fallen into the second rank, if not lower even, in this respect.

But this is no slight matter. It would be easy to show how direct and how great has been the influence of these art gatherings on our national manufactures. Can we afford to run the risk of being outstripped in this last field also?

### RIVAL SYSTEMS OF HEATING.

TWO articles on heating, by Dr. A. N. Bell and Professor W. P. Trowbridge, have appeared in a late number of the *North American Review*, from which we take the following extracts:—

Dr. Bell writes:—So important and rapid have been the improvements in the construction of stoves in the United States with the last eight or ten years, that it is difficult to find a market for those of older date. In England, where the people continue to be wedded to open grates, and where most is said by scientific persons against the use of stoves, improvements have been exceedingly slow and complicated, and the practicability of maintaining a sufficient and equable temperature and a wholesome atmosphere in a room warmed by a stove is far from being realised; still less the convenience of warming several rooms at the same time by the same means, hot-air furnaces scarcely being known.

The essentials for healthy stove-heat are a brick-lined fire-chamber, exhaust-flue for foul air, means for supplying moisture, and provision for fresh-air supply. A brick lining is requisite for the double purpose of preventing overheating, and for retaining heat in the stove. For the supply of moisture, the means are simple and easy of control, but often inadequate. An efficient foul-air shaft may be fitted to the commonest of close stoves by simply enclosing the smoke-pipe in a jacket—that is, in a pipe of two or three inches greater diameter. This should be braced round the smoke-pipe, and left open at the end next the stove. At its entry into the chimney, or in its passage through the roof of a car, as the case may be, a perforated collar should separate it from the smoke-pipe. For stoves with a short, horizontal smoke-pipe, passing through a fire-board, the latter should always be raised about three inches from the floor. A smoke-pipe thus jacketed, or fire-board so raised at the bottom, affords ample provision for the escape of foul air.

The introduction of fresh air is a comparatively easy matter, when by no more special provision, then by a strip of board under the window-sash, closely fitted. The lap of the sash at the middle admits the air with a direction to the ceiling, and, consequently, without draft on anyone in the room.

The experiments of Petenkoff have shown that, under the common conditions of the atmosphere, a very considerable exchange of gases takes place through dry plastered walls, brick, and stone. And it is the common experience of sick persons that they are sensitive to drafts through walls when the wind blows, and that they frequently take cold by exposure to the windy side of the house.

All flues for the exit of foul air should be perfectly smooth and tight. Rough surfaces not only retard but retain emanations which come in contact with them. Moreover, exhaust-flues should never be placed in outer cold walls, because the greater density of the outer cold air prevents the ready ascent of the warmed and rarefied air from within. Another important consideration is the size of air-shafts. This can only be approximate, however, be-

cause the amount of air which will pass through a shaft depends in a great degree upon the relative temperatures of the inner and outer atmospheres, and the conditions of the weather, particularly the direction of the wind. As a practical average, the best observers recommend that the sectional area of both inlet and outlet shafts be 24 square inches per head; or, for buildings of three storeys, one square inch for every 50 cubic feet of space; rooms below, one square inch for every 55 cubic feet; for ground floors, one square inch for every 60 cubic feet. It should be borne in mind that the friction in long flues considerably lessens the extractive power, and that the column of air in the flue increases in density as it ascends. In prisons, where the cubic space per head is comparatively small, the sectional area of the air-shafts should be at least 20 square inches per head.

Open fire-stoves combine the advantages of the open fireplace and the close stove, provide for fresh air, and economise heat. The important improvements in stoves of this kind have not only well-nigh supplanted the open fire-grate in supplying all that was ever claimed for it, but excel it in all the requisites of economy and comfort.

Hot-air furnaces are simply enclosed stoves placed outside the apartments to be warmed, and usually in cellars or basements of the buildings in which they are used. The manner of warming is virtually the same as by indirect steam heat—by the passage of air over the surface of the heated furnace or steam-heated pipes, as the case may be, through flues or pipes provided with registers. The most essential condition of satisfactory warming by a hot-air furnace is a good chimney-draught, which should always be stronger than that of the hot-air pipes through which the warmed air is conveyed into the rooms, and this can be measured by the force with which it passes through the registers. A chimney-draught thus regulated effectively removes all emanations; for, if the chimney-draught exceeds that of the hot-air pipes, all the gaseous emanations from the inside of the furnace, and if it have crevices, or is of cast-iron and overheated, all around it on the outside, will be drawn into the chimney. Closely connected with this requirement for the chimney-draught is the regulating apparatus for governing the combustion of fuel—the draught of the furnace. This should all be below the grate; there should be no dampers in the smoke-pipe or chimney, and all joints below and about the grate should be air-tight. The fire-pot should be lined with brick and entirely within the furnace, but separate from it, so that the fresh air to be warmed cannot come in contact with the fuel-chamber.

It should go without saying that the air which passes from furnaces into living-rooms should always be taken from out of doors, and be conveyed in perfectly clean air-tight shafts to and around the base of the furnace. Preferably, the inlet of the shaft, or cold-air box, should be carried down and curved at a level (of its upper surface) with the bottom, and full width of the furnace. Thus applied, the air is equally distributed for warming and ascent through the hot-air pipes to the apartments to be warmed. On the outside the cold-air shaft should be turned up several feet from the surface of the ground, and its mouth protected from dust by an air-strainer. A simple but effectual way is to cover the mouth with wire cloth, and over this to lay a piece of loose cotton wadding. This may be kept in place with a weight made of a few crossings of heavy wire, and it should be changed every few months. And here, too, outside the house, should be placed the diaphragm for regulating the amount of cold air supply, and not, as commonly, in the cellar.

As the best means of regulating the temperature and purity of the atmosphere from hot-air furnaces, it is necessary to provide sufficiently large channels for both the inlet of fresh air and its distribution through the hot-air pipes. The area of the smallest part of the inlet (or inlets, for it is sometimes better to have more than one) should be about one-sixth of a square foot for every pound of coal estimated to be burned hourly, in cold weather; and to prevent, in a measure, the inconvenience of one hot-air pipe drawing from another, the collective area of the hot-air pipes should not be more than one-sixth greater than the area of the cold-air inlet. These proportions will admit the hot air at a temperature of about 120 degs. when at zero outside, and the velocity through the registers will not exceed five feet per second.

A large heating surface of the furnace is a well-recognised condition of both economy and efficiency. As a rule, there should be ten square feet of heating surface to every pound of coal consumed per hour, when in active combustion; and the grate area should be about one-fiftieth of that of the heating surface. For the deficiency of heat, or the failure of some of the hot-air pipes of hot-air furnaces in certain winds and weathers in large houses or specially exposed rooms, the best addendum is an open fire-grate. With this provision in northerly rooms to be used occasionally, hot-air furnaces may be made to produce all the advantages of steam-heat in even the largest dwelling-houses.

Professor Trowbridge writes:—The system of steam-heating apparatus, or its practical equivalent in limited circuits, the hot-water apparatus, is being gradually extended even for ordinary dwellings, while for large blocks, such as apartment-houses, hotels, manufacturing establishments, school-houses, and other large structures, the system is so greatly in demand as to have given

rise to new and extensive industries devoted to the manufacture and instalment of the necessary apparatus.

Steam heating is characterised by the fact that the heat is generated in the furnace of a boiler either within or without the walls of the building to be heated, the heat of combustion being transferred to water, which, being vapourised, constitutes the medium by which the heat is conveyed in comparatively small pipes to the points where it is utilised for heating purposes. Two distinct methods of utilising this heat are practised. In one the steam pipes are carried, by the most convenient course, directly into the room or space to be heated, where, by convolutions of the pipe, or what are known as radiators, an extended heating surface is furnished to the room. These coils, or radiators, give off heat both by radiation and by contact with the air, which is kept slowly circulating, as in the case of a close stove; and it is evident that only a feeble, or at least uncertain, ventilation is possible, except through special arrangements made for introducing fresh air. These heated coils are, in effect, identical with close stoves, the only difference being that the surfaces of the coils can never be heated to a degree higher than that of the steam—practically, never higher than three hundred and ten nor lower than two hundred and fifteen or two hundred and twenty degrees Fahr., while the surface of the close stove may, under some circumstances, approach nine hundred and fifty degrees. Active and sufficient ventilation may be attained with these coils, however, if they are placed in such a way that cool air, introduced through openings—as, for example, under windows—will mingle directly with the heated air rising from the radiators, and then be deflected upward to be mixed with the general circulation, and discharged through ventilating flues. Of course, such active ventilation can only be attained at the expense of additional heat.

The other method, called by a strange misconception “indirect radiation,” consists in conveying the steam from the boiler to small chambers constructed for the purpose, in the basement, directly beneath the rooms to be warmed. Here the steam pipe is extended into a coil, or an equivalent arrangement, by which a large amount of steam-heated surface is exposed. Flues for heated air lead from the roof of the chamber to the various rooms to be heated; an inlet duct for fresh air enters the bottom of the chamber, and the coils or “radiators” are so arranged that the air in rising comes in contact with the heated surfaces, and passes to the apartments to be warmed with the temperature increased to seventy or one hundred degrees Fahrenheit. Low temperature currents only are generated; and as the proper action of the apparatus can be kept up only by a continuity of flow into and out of the space to be heated, the two effects of heating and ventilation are most effectively combined.

A comparison of these various methods must include the cost of the apparatus, the cost of attendance, the cost of fuel, and the incidental advantages and disadvantages belonging to each. The open fireplace possesses the advantage of giving thorough ventilation, but it is the most expensive in fuel. The close stove is highly advantageous in point of economy, where there is little ventilation, and as this is apt to be the rule, it is perhaps the least healthful of all methods as generally applied. Both of these methods become costly in attendance as well as in fuel when the heating of dwellings of many rooms is required, and are inapplicable to large structures and public buildings as they are now constructed. The hot-air furnace system is of all the most difficult to manage, so far as uniformity and control of temperature is concerned. The danger from fire, the dust, the defective ventilation, and the impracticability of heating more than a limited space by a single hot-air furnace are other defects inherent in this system. Steam heating involves greater first cost in apparatus than any other system. When this cost and the cost of attendance and repair are taken for a series of years, however, it is conceded that there is but little choice between hot-air furnaces and steam-heating apparatus as regards economy.

It is only to be remarked that the most thoughtful among our physicians and sanitary advisers realise with anxiety the fact that there is a growing abuse of all these systems, except the open fire, in providing too much heat and too little ventilation. There is no mode of heating which lends itself to the correction of this evil so readily, however, as the steam-heating method. With proper care on the part of architects in arranging inlet ducts for fresh air, and ventilating flues heated by steam coils to accelerate the draught, any desirable degree of ventilation with low temperature currents may be secured. Such arrangements should, however, be studied in advance, and form principal elements in the design of a building, instead of being wholly subordinate, as is commonly the custom, to less important architectural features. It should be regarded as a fundamental principle in architecture that the first and most important problem to be studied, after the general design of a building is determined, is the proper positions and magnitudes of heating and ventilating appliances for the structure as a whole, and for each room in particular; and not only should the details of the main and cross walls be modified and adapted to these arrangements where it is necessary, but no question of mere architectural propriety or appearance, nor even of convenience in use, should be allowed to interfere with objects so important to health as good and sufficient warming and ventilation.

## NOTES AND COMMENTS.

THE Committee of the House of Commons have decided against the Bill which was to enable the inhabitants of what is called the Lower Thames Valley to purchase land near Mortlake as a receptacle for sewage. It is understood that the Bill was thrown out not so much on account of its demerits, as from a difficulty in connection with two of the districts affected by the scheme. The result will be gratifying to inhabitants on the banks of the Thames, and to people who use the river for boating. But the original difficulty still remains. The inhabitants of the Lower Thames Valley district have been trying for years to satisfy the law in regard to sewage disposal, and they must have expended at least 50,000*l.* on engineers and lawyers. They are prohibited from using the Thames, and they cannot obtain land within a reasonable distance. Unless they undergo the enormous expense of bringing their sewers to the coast, it would appear that they must break the law. It is now doubtful whether the separate districts in the Thames Valley will be able to get rid of the sewage.

It is only an Irish member who could imagine there was a danger to the State in the simple patterns which are devised as a test of elementary drawing. In one which was given in the Irish examinations by Mr. CARROLL, a teacher of art in London, the principal figure was an old Celtic harp, an object which combines graceful contours with straight lines. To add to the task, a heart was placed above the harp. It was this simple thing which was interpreted as being a symbol of treason against the British Empire, and accordingly was brought under the notice of the House of Commons. The Archbishop of CANTERBURY might with as much reason allege that the pagan statues and ornament used in schools are instruments for the subversion of Christianity. In the harp case it was gravely explained that the figure was without political meaning, but it was hardly necessary to waste words on such a subject.

THE Corporation of London are about to decide on the figures which are to adorn Blackfriars Bridge. There are four pedestals, and six competitors were invited to compete for the equestrian groups. Mr. WOOLNER declines to take part in any competition, and there are consequently only five artists for four prizes—a state of things which would be impossible in architecture. The five subjects comprise four kings and one mayor. Mr. BELT has selected *William III.*, Mr. BIRCH *Henry V.*, Mr. BROCK *Edward III.*, Mr. THORNYCROFT *Edward I.*, and Mr. ADAMS *Fitz-Alwyn*, the first mayor of the City. The competition has hardly been conducted with the prudence that was expected from a body like the London Corporation. No opportunity has been given for discussing what kind of sculpture would be most suitable, and the experiment was not tried of opposing a group to the equestrian statue which was placed temporarily on a pedestal. Critics would not be unanimous about the fitness of equestrian figures for the bridge.

MR. ROBERT CHRISTIE, of George Street, Portman Square, has imported a collection of Japanese wall-papers which are of new designs. The ground in many of them is lighter than in the papers which were first produced for the English market, and, indeed, for some patterns it is a pure white. The designs are all good in character; some appear to have been derived from French and Italian Renaissance work, and the printing of the pieces has been carefully executed. The collection should be seen before it is entirely dispersed. Fine Indian fabrics and rich French hangings, which are also new, are to be found in the same house, with examples of ancient and modern furniture. They are all of a superior class. Mr. CHRISTIE has the advantage of being an artist, and whatever he purchases is certain to possess beauty in form and colour.

THE conversazione of the Society of Arts at the Health Exhibition on Wednesday was thoroughly successful. The crowds which attend on those occasions testify both to the influence and the hospitality of the Society. Both within and without the Exhibition there was much to gratify the sight, and in addition there were the rival English, French, and German

bands. As a foil there was a musical entertainment by Chinese artists, and it would be difficult to imagine noise more discordant. The grounds were lighted in a new and pleasing manner; and, in fact, the entire arrangements left little to be desired.

THE report has been issued of the Cockburn Association, which is established in Edinburgh, and has for its object the amenity of that city. An objection is raised in it against holding exhibitions by which the beauty of some park or pleasure ground is sacrificed, and that a site should be allotted outside the city for cattle and other shows. The Council have been informed by the Secretary of State for War that the Parliament House in Edinburgh Castle will be restored, as preliminary arrangements are being made by which it is hoped that this building may be diverted from its present appropriation to uses more in harmony with its history and associations. The purchase of Blackford Hill by the municipality is considered to be the most notable addition made to the amenity of the city since the formation of the Association. The Council think that something might and ought to be done to improve the appearance of the Waverley Station at its west end, adjoining the Waverley Bridge, which has long been in a disgraceful condition. The city has, they say, suffered irreparable injury to its amenity by the railway being constructed through its midst, and the least thing the directors of the railway company could be asked to do was to make their parcel-office as inoffensive as possible. Regarding the sale of the ground adjoining Holyrood Palace for the purposes of a brassfoundry, the report says the acquisition of any of the ground in that neighbourhood which can be had seems to deserve the serious attention of the Government, and it is earnestly hoped that they will spare no effort to prevent such a work as a brassfoundry from vulgarising the vicinity of the ancient residence of the kings of Scotland. In reply to a communication from the Association with reference to the contemplated erection of a foundry in the vicinity of Holyrood Palace, the Board of Works have stated that they do not feel it incumbent upon them to take any action in the matter.

MR. WALTER SMITH, of the Bradford Technical College, who has had much experience in conducting English and American art schools, has written a paper on the present position of the schools in this country. Mr. SMITH maintains that although the Department schools may not be as much of a failure to-day as Schools of Design were felt to be in 1852, yet the existence of a Royal Commission on Technical Education in Art, Science, and Industry, indicates that fresh life is needed in them, and it is highly probable that before very long Parliament may be called upon to consider and legislate upon a national scheme of technical or secondary education, involving the reorganisation of the Science and Art Department, and the entire remodelling of schools of art. Mr. SMITH is emphatic in condemning the popular fallacy that schools of art should be self-supporting. It is utterly illogical, and very impractical, he says, to suppose that young artisans can pay the full value out of their weekly wages of the technical education they need in schools of art, when the aristocracy and the wealthy middle classes do not and are not called upon to pay the whole cost of the education of their sons in the public schools, grammar schools, and universities. Mr. SMITH believes that schools of art will never enjoy full and healthy and useful life so long as they are, as now, largely dependent upon voluntary support, but will do so when they are recognised as public institutions existing for the public good, under municipal management and control.

NEW baths are to be erected in Bradford, and it was at first proposed that the plans should be prepared by the Borough Surveyor. The committee having charge of the scheme wished to have a design by an architect, and suggested that there should be a competition among the Bradford architects. The question was brought before the Council on Wednesday, and by the casting vote of the Mayor it was decided to entrust the work to the Borough Surveyor. As a set-off to this, it may be mentioned that the Council are about to erect municipal buildings, and the works are to be entrusted to Messrs. W. & R. MAWSON, the architects of the town-hall which imparts so much dignity to Bradford.

SHOWROOMS AND OFFICES, EDMUND STREET, BIRMINGHAM, FOR MESSRS. JONES & WILLIS.

THESE premises have been just erected from designs by Messrs. PHIPSON & SON, as offices and showrooms in connection with Messrs. JONES & WILLIS's works, Porchester Street, Birmingham, and Euston Road, London, and are built especially for the better display of their manufacture in art metal, wood, and stonework, combined with their old-established furnishing business. The new buildings are necessary, as the premises in Temple Row, Birmingham, which were used as showrooms by Messrs. JONES & WILLIS are about to be demolished, having been acquired by the Conservative Club Company as a site for the new club.

## PARK HALL AND NEW BUILDINGS, CARDIFF.

THE large block of buildings shown in the illustration has been for some time in course of erection on the site of the old Cardiff Theatre in Crockherbtown. It comprises two public halls, one large and one small, a first-class hotel, ten shops, and a coffee tavern, and is owned by the Park Hall and Hotel Company (Limited). In size the building far surpasses all others in Cardiff. There are frontages to Park Place and Crockherbtown. The principal materials used are Forest of Dean and Newbridge stone, relieved with Bath stone and terra-cotta dressings. The ten shops face Crockherbtown, the chief thoroughfare. They are all spacious, and eight of them have dwelling-houses attached. The shop at the south-east corner of the building, which will be fitted up as a coffee palace, has in addition a large coffee or dining-room, 49 feet by 21 feet 6 inches, and also a ladies'-room, billiard-room, smoking-room, and everything necessary for the trade. The greater part of the Park Place façade is occupied by the hotel. It has a coffee-room, 44 feet by 29 feet; a commercial-room, 44 feet by 30 feet; a ladies' coffee-room, a private dining-room, a large billiard-room, and about one hundred sitting-rooms and bedrooms, with all the conveniences usually to be found in first-class hotels. The large public hall, which adjoins the hotel, has its principal frontage to Park Place, and is entered immediately from that street, with which the ground floor is level. In designing this hall the architects took especial care to provide against the evil results of a panic. With this view they put in no less than ten doors for egress, all of which open outwards. The auditorium of the large hall is 127 feet long, 65 feet wide, and 53 feet high, and it will give sitting accommodation to fully 2,500 persons. The interior will be decorated with a panelled and coved ceiling, supported by fluted pilasters having Corinthian capitals, and provided with a balcony or dress circle. The orchestra will hold 250 performers, and the hall will contain an organ, which the directors have ordered from Messrs. HENRY WILLIS & SONS, and which will be the largest in the Principality. At the end of the hall, opposite the platform, is a room 44 feet by 33 feet, which is so arranged that it can be added to the main hall for very large public meetings. The latter will thus be able to accommodate an additional 600 persons when necessary. Connected with the large hall are several retiring rooms, and also a spacious vestibule or "crush-room," which will be carefully warmed and ventilated. The grand staircase which leads to the dress balcony is in this part of the building. Near the platform there are retiring rooms for performers, as well as rooms suitable for committee meetings. The great hall will be lighted by the patent sun-burners of Messrs. STRODE & COMPANY, London, who have also supplied the special appliances for ventilating the building. The hall will be warmed by a series of hot-water pipes, which are to be arranged so as to give a uniform temperature in every part. The small hall, which is 60 feet long, 30 feet wide, and 33 feet high, will seat 600 people, and will be used for ordinary lectures, concerts, and public meetings. There are private rooms for committees at the back of this hall. The whole of the public buildings have been planned in such a manner that in the case of an exhibition or bazaar they can be made to communicate one with the other, and by this means the whole of the extensive range of rooms can be utilised. The contractor for the buildings is Mr. F. S. Lock, of Cardiff, whose tender amounted to 33,900/.

The architects, from whose designs the works are carried out, are Messrs. W. G. HABERSHON & FAWCKNER, of 38 Bloomsbury Square, Newport, and Cardiff.

## ADDITION TO HOUSE IN OSWALD ROAD, EDINBURGH.

THIS house, situated in the southern suburb of Edinburgh, commanding a magnificent view of Blackford Hill and of the Pentland Hills beyond, was built about twelve years ago. The addition shown by the illustration has been recently made, and consists on the ground-floor of improved kitchen office accommodation, on the first floor of day and night nursery, with bath-room, scullery, &c., attached, and on the upper floor of two bedrooms, dressing-room, &c.

The plans both of the original house and of the addition were prepared by Mr. R. MORHAM, architect, Edinburgh.

## ENTRANCE, TIDDINGTON HOUSE, OXON.

ONE of our illustrations is a view of the entrance façade to Tiddington House, Oxfordshire, the residence of the Rev. JOSHUA BENNETT. The house is an old building of the Georgian period, and though originally plain and unpretentious, its bold coved cornices under the eaves, its rubbed and shaped arches, moulded strings, and thick sash bars, made it of considerable interest to the admirers of the "Queen Anne" school of architecture, and led to the adoption of that style in the alterations and additions made last year, of which the work shown in our illustration formed a small part. Between the "entrance façade" and the wall of the house there is a space of some 20 feet in length, which is enclosed by a substantially-built conservatory-like erection of Queen Anne design, forming an outer hall.

The works were executed by Messrs. HOLLY & BUTLER, of Nettlebed. The brick-carving was beautifully done by the late Mr. FINLAY; and the architects were Messrs. MORRIS & STALLWOOD, of Reading.

## ARCHITECTS' CONFERENCE AT THE HEALTH EXHIBITION.

MR. EWAN CHRISTIAN, President of the Royal Institute of British Architects, took the chair on Thursday at 2 p.m., on occasion of a conference of the Royal Institute of British Architects held at the International Health Exhibition. The Chairman, in opening the conference, said that they were met together to discuss a most important subject which affected every one of us, our health, spirits, and life; and a subject eminently practical if properly treated. The Institute, of course, did not hold itself responsible for opinions which might be given by any individual speaker, and certainly not for his own opinions. This question was one not for the rich, but for the multitude, the great middle-class and the working-class. When they looked around to see what provisions had been made for the middle and working-classes, their hearts almost failed them. The rich could take care of themselves, as with the rich it was not a question of cost; but the great bulk of people had to live in houses in which there had not been that care taken that was necessary, nor was there the money even where people wished to take that care. There were builders who built thoroughly well, and there were builders who built to sell and for the immediate prospect of gain, and these were the people we had to fear. One important question of health was the choice of a site. Some people supposed that when a gravelly soil was secured for the site, that the house would be dry and that nothing more need be done. Other people had a great dread of clay. But in London we were to a great extent obliged to live on clay soil, and it was the business of the architect to consider this, and it should be the business of the builder also. A man had, however, said to him that such work was not seen, that what was not seen would not be paid for, and therefore the work would be done at a dead loss. As regarded the laying out of estates by architects, too little attention was paid to the question of aspect, and, if there was one friend we ought to welcome into our houses, it was the sun. There could not be a wholesome house in which the sun did not enter. In some sites it was, so they said, impossible to get the sunshine into the house. He did not believe it. Architects were born to contend with difficulties, and, if they could not get the sunshine in direct, they must lay traps to catch it. People when looking out for a house should always bear in mind that wise aphorism of Bacon, "He who builds on an ill site, commits himself to prison," and much the same might be said of the man who buys a bad site. There was an extraordinary difference in light under different circumstances. A really bright sky was rarely seen in Staffordshire, the same was the case in Gloucestershire and other parts of England. The exact contrary could be said of districts where the subsoil was of a dry nature. Anywhere in Norfolk you would find a bright sky owing to the subsoil, which was a beautiful dry light sand. For the health of the inmates of a house there should be a

sufficiency not only of air, but of light, especially the light of the sky, and this was generally ignored by builders who built to sell, who tried to make a pretty house by the use of obscured glass for the windows, which obscured the light of the sky and deprived the inmates of the advantages to be got from that light. If one looked at the faces of those children brought up in dark rooms and those brought up in light rooms, the faces of the one would be found pale, and of the other bright. It was said that English children could not live in India, but he had found that when light was freely admitted to them they could live there just as well as in old England. But, after all, when a house was properly built, and people went to live in it, unless common sense reigned within the house, all the architect or builder could do to make the house healthy would be spoilt by the way in which the house was treated.

Professor T. Roger Smith then read a paper on the "Construction of Houses with Regard to Sanitary Arrangements," which will be found in another part of the paper.

Mr. Fred. W. H. Hunt next read a paper on "The Sanitary Arrangements of Houses in London during the last Eighty Years." This paper will appear in next week's issue of *The Architect*.

Professor Kerr then opened a discussion, and expressed the hope that this opportunity would be embraced by architects of London to expound more particularly those principles which they, having to do with those matters professionally, understood so much better than any other section of the community. Mr. Hunt had explained to them the way in which sanitary appliances had found their way into houses to our discomfort. Time was, and not so long ago, when none were found in the house. All were outside, and there were none of the smells indicative of the presence of poison with which sanitary science had to deal, sanitary science now having enough to do in dealing with the evils which sanitary science had created. Underground we had created an immense number of filthy channels in which poison was generated every moment. Every room in the house was connected with this underground system, and the poison generated there admitted into them. Professor Kerr then read some propositions which he had formulated as his contribution to the solution of the difficulty, which may be summarised as follows:—that atmospheric air had for its principal function the universal work of cleansing; that decomposition in the open air was innocuous; that houses in this country were closed boxes, to the absolute exclusion of the outer air; that they were filled with vapours from the ground beneath; that the houses were in connection with this great system of sewers and poison; that the communications from the house to the underground system were really communications to the house again; that cleansing air might find its way into the house, but that the sewer gas forced its way in with still greater energy. There were three ways of meeting these evils. One plan, impossible to carry out, would be to do without these appliances altogether. A second plan, he was sorry to say, was to direct their ingenuity to improving and increasing the efficacy of these already too complicated appliances. In the third place was a plan that he himself had thought out, to form a vertical compartment or annexe, open at both ends, and running from top to bottom of the house, to contain all water-closets, sculleries, &c., &c., with shaft for pipes of water and gas service, &c., the annexe to communicate only with the staircase. In connection, also, a subway under the basement, with manhole at each end, to contain water and gas mains, &c.

Sir H. Ackland, F.R.S., said he thought he never heard anything more opportune or instructive than the papers they had just heard. The description given by Mr. Hunt of this very curious subject in the world's history in our time, was well worthy of their attention in a most serious way. He said it was a curious subject, because, as Professor Smith reminded them, a good deal of these matters were better understood a couple of thousand years ago than now, and some of the works of the Romans in Italy, Rome, and in the neighbourhood of Carthage, especially the water-supply, were worthy of the utmost admiration of the engineers of the present day, though constructed with unscientific knowledge. Some forty years ago, when they had directed attention to these matters, the public had mistaken their action, and said that they did not believe doctors were going to do anything to try and abate diseases. They could not understand that they wished to stop the ravages of disease. Therefore he was glad to see that architects, chemists, doctors, &c., having put pedantry aside were taking steps to popularise the subject, and let the public know the absolute necessity of carrying out this work, and that architects were determined to set these matters right.

Mr. Lewis Angell, C.E., disagreed with Professor Kerr's remarks, and said that the evils complained of were not due to sanitary science but to the want of proper sanitary science. No wonder houses were foul when people came to see the condition of the drains. These matters were not overlooked by architects; they were left entirely to the working labourer.

The discussion closed with some remarks from Mr. W. C. Street.

At 4 p.m. the conference was resumed, and a paper read by Mr. S. Flint Clarkson on "Drainage under Dwellings," which will be given next week.

A discussion was opened by Mr. Thomas Worthington and continued by other speakers, and the proceedings were adjourned till Friday.

### THE BLENHEIM PICTURES.

A DEPUTATION waited on the Chancellor of the Exchequer to urge the importance of the Government purchasing some of the pictures from the Blenheim collection. The Duke of Westminster headed the deputation, and stated that the Duke of Marlborough had offered to sell to the nation the *Madonna and Child, with Saints*, by Raphael, and the equestrian portrait of Charles the First, by Vandyck, for 160,000 guineas. Sir Frederick Leighton said it would be a great loss to the nation if the National Gallery did not acquire the principal Rubenses as well as the Raphael and Vandyck. Mr. Agnew supported the view of Sir F. Leighton. It was stated, in answer to the Chancellor of the Exchequer, that 24,000*l.* was the highest price ever paid for a picture. Mr. Childers, without expressing an opinion, promised that the views of the deputation should be laid before the members of the Cabinet. It is now said that the Government will not buy the pictures.

### THE EXHIBITION AT PESTH.

THE Secretary of State for Foreign Affairs has received a note from the Austro-Hungarian Ambassador respecting the facilities which will be granted to goods sent to the Exhibition which is to be held at Buda-Pesth in 1885. The Austrian and the Hungarian railway companies, the Danube Steam Navigation Company, and the Advia Navigation Company will carry such goods at reduced rates. The Austro-Hungarian Lloyd has also made certain alterations in its rates for the same goods, and various railway companies in Germany, Holland, France, and Russia have agreed, under certain conditions, to carry back, gratis, any goods not sold at the close of the Exhibition. The Finance Ministry of Hungary has also granted various Customs facilities for foreign goods destined for the Exhibition. The Governments of Germany, Holland, Italy, Belgium, France, and the United States of North America have consented to re-admit free of duty goods which are brought back unsold from the Exhibition in question. Further and more detailed information can be obtained at the Austro-Hungarian Embassy, Belgrave Square.

### MANCHESTER CATHEDRAL.

A MEETING of parishioners has been held in Manchester to consider the advisability of removing the south gallery in the cathedral. The Dean, who presided, said that regarded as a diminution of the accommodation in the church, he should regret the removal of the gallery, unless he were persuaded there would be a corresponding addition to the sittings in some other part of the church. That was apparently in the contemplation of the architect and the churchwardens, who believed they could provide accommodation in another part which would quite replace the seats lost by the proposed removal of the south gallery. The strongest reason in favour of the removal of the gallery was that it was part of the scheme to take back into the church what was now called the cathedral library. He was on that ground entirely in favour of the removal of the gallery. That would do much towards replacing the seats lost in the gallery; therefore upon the whole his mind inclined towards the removal of the gallery. He could not avoid expressing his great regret that the opportunity was not taken when an extension was first suggested for extending the north aisle further westwards, leaving it perhaps for a future generation to extend the whole church westward. After some discussion it was resolved to apply for a faculty. Two books on the history and architecture of the cathedral are about to be published. One by the Rev. Ernest F. Letts, M.A., precentor and minor canon, aims at being not only an exhaustive account of the persons and incidents connected with the church from the very earliest times to the present day, but a careful architectural summary of its construction. In this latter portion of the work Mr. Letts will be assisted by Mr. John Crowther, the present architect of the cathedral. In addition to a chronicle of many incidents of local history, the work will contain copies of the early deeds and charters, reproduced in *fac-simile* by photozincography. The book will also abound with illustrations, many of them in colours, depicting the heraldry, brasses, tombs, monuments, stained glass, &c. The architectural drawings will all be photographed from the originals, as well as numerous maps, plans, and other matter. An effort will be made to include every object of interest connected with the church and its ancient chapels. The book will be published in four large quarto volumes, each volume containing a distinct period. The first volume, which is expected to appear about next Christmas, will bring the history of the collegiate church down to the granting of the first charter, in the years 1421-22. Messrs. Abel Heywood & Co., of Manchester,

are the publishers. The other work, which will probably appear earlier than the elaborate monograph by Canon Letts, is "An Historical Account and Illustrated Description of the Cathedral Church of Manchester," being the essay submitted to the council of the Manchester Society of Architects for a prize given by the society during the session 1883 by Mr. T. Locke Worthington. In this an historical sketch is first given, in which the origin and formation of the present plan of the main body of the church are explained. Reference is made to the architecture, position, and form of the old parish church prior to the foundation of the collegiate church in 1422. The origin and history of the various chantries is then given, thereby explaining the addition of the outer aisles and chapels. A description of the interior follows, including particulars of the monuments, brasses, and stained glass. After this a description of the tower is given, and an external survey of the church, and, finally, a dated record and notes on the various modern alterations and restorations.

### BIRMINGHAM ARCHITECTURAL ASSOCIATION.

THE annual dinner in connection with the Birmingham Architectural Association took place on the 4th inst., at the Grand Hotel, Birmingham. Mr. J. J. Bateman presided, and there were also present Messrs. Franklin Cross (hon. secretary), J. Cotton, V. Scruton, E. Wood, J. T. Eayres, D. Dickinson, W. H. Kendrick, F. G. Hughes, J. W. Tonks, J. Pratt, &c. In proposing "The Association," the President said he regretted that the young members of the profession had not received the assistance they ought to have received from their seniors in Birmingham. The success of the association was marked. During the past year it had greatly improved, financially and numerically, and he trusted the heads of offices would do their best to induce students to join the association. The President explained at length the results of the last triennial conference in London. At the present time he thought there was an opening for the junior members to make a departure in architectural design. In the past there had always been a leading spirit joining the different styles which the profession followed, but such was not the case at the present time.

Mr. Cross (hon. secretary) replied to the toast, stating that the association was flourishing, but urging upon members of the profession to do their utmost to support it in the future.

### SANITARY FURNITURE.

A LECTURE on house furniture, considered in respect to sanitation, was delivered by Mr. Robert W. Edis, F.S.A., in the Conference Hall at the Health Exhibition on Monday last. Mr. Edis, at the outset, remarked that, having been engaged for some time as one of the jurors in connection with the exhibition, he had been astonished to find that some of his colleagues disagreed with his views, and therefore it was with the utmost diffidence that he laid before them what he considered were the right considerations as to health in the house allied with artistic and decorative principles. When pure air, pure water and proper drainage had been secured, many people considered they had done everything necessary, but Mr. Edis pointed out that as regarded purity of air it must be borne in mind that the air of our rooms was not only influenced by impure smells, but by the objects of furniture, &c., placed in those rooms. There were persons, it struck him, to whom the sense of sight was nothing. They visited different countries, and admired the grand scenery they passed through, and showed that they did possess a sense of what was beautiful in nature and in art. But in minor things the sense of sight seemed almost neglected. No one there present, he believed, would eat food badly cooked, or permit of smells pervading the house, but they allowed of wall papers, carpets, hangings, &c., irrespective of propriety of design, fitness for the purpose, &c. Take the floor coverings of a room. We were content to cover the whole of a floor with a thick carpet, which was only taken up once or at most twice a year, and then revealed an amount of filth ghastly to look at. Windows were hung with Venetian blinds, on which dust and dirt accumulated. This dust, dirt, and filth must contribute a certain stuffiness to the rooms. Windows and doors of bedrooms were closely shut, and the inmates breathed an air which was absolutely deleterious, and which made the hours of sleep restless and uninvigorating. If there were any truth at all that illness was brought about by impure air, that impure rooms brought about lassitude and illness and all that was objectionable in life, he took it that these things ought, from a sanitarian point of view, to be avoided. At any rate, if it was hopeless to get rid of them altogether, they should be minimised as far as could be. Houses should be made as good and as clean as possible inside, and, if our houses were cared for, the towns would look after themselves. Mr. Edis pointed out that care should be taken to avoid making receptacles for dust in our rooms—cumbrous furniture, as wardrobes seven feet high, on the top of which dust and dirt lodged out of reach of the servant; heavy hangings, flock wall-papers, &c. The designs of papers and hangings also were noticed. People should not be annoyed or worried on waking up in a room

by seeing the absurd repetitions of endless bunches of flowers which obtruded themselves on our notice and set one to count them up, or the conventional cherubs tied together with wreaths of roses. One wanted the cherubs to shut their mouths or to open them, or anything so long as they would only get out of the way. Representation of motion, such as the design of birds in flight—only they did not move—should be avoided. All this must in some way affect the health of the inmates. From an æsthetic point of view, if he understood the æsthetes right, he must say that he had nothing in common with them, and, if they were at all answerable for these things, let them have nothing to do with æsthetes or æsthetic furniture, &c. There was one exhibit, however, of bedroom and other furniture, Mr. Edis said, which practically carried out his own views, and his audience would be able to judge for themselves whether it was worth looking at. Mr. Edis, speaking of town houses, did not, in case of a family growing up, advocate the putting children in one room, or nursery, and the ranging a little row of beds together for them at night. As they grew up, he thought each should have their separate room arranged as sitting-room and bedroom, and this could be done by cutting off part of the room by a curtain or some such expedient. In regard of floors, he recommended staining or painting them, and stopping up every crevice and crack, and the use of mats instead of carpets. The room could then be kept perfectly clean with little trouble. A sickly odour was sometimes noticed in rooms, which could not be accounted for. It arose from the size, which was in a state of putrefaction. Wherever this was the case, he recommended that the paper should at once be taken down. Mr. Edis then devoted some remarks to the necessity of securing proper ventilation, especially in sleeping rooms, the practice being almost universal to close up a bedroom hermetically so to speak. He regretted that the time at his disposal was so short, and that his subject was so large, and he felt that in the short time he had addressed them he had barely been able to touch on what he would have liked to have said.

### IRON ROOFS.\*

IF the development of iron roofs could be fully followed out in a book, we should have an almost complete treatise on practical statics. That development is partly owing to theoretical investigations, but mainly to the daring which comes from experience. The first great roof was one in the old Lime Street Station in Liverpool, which was designed and constructed in 1850 by the late Richard Turner. It was so much of a novelty that Mr. Joseph Locke, who was one of the wisest of railway engineers, was opposed to its erection, as he was doubtful about the security of the structure. The span was 153 feet 6 inches, and the principals were 21 feet 6 inches apart. When the station was enlarged it was found practicable to construct a roof having an average span of 212 feet, with principals 30 feet apart. The roof of the St. Pancras Station has a clear span of 240 feet, and the St. Enoch Station is covered by a roof 198 feet span, which is independent of any transverse ties. If railway managers will continue to believe in unimpeded stations—which, however, is not a certainty—it is possible that roofs of greater spans will be constructed, and that one of double the width of the original Lime Street roof may be seen in this country. We may even see a roof that will rival Colonel Emy's projected timber roof, which was to be 328 feet wide. Turner knew little of theory, and it may be doubted if he ever used any formula except some rule-of-thumb calculation which he had worked out for himself; and in many later roofs his example has been followed. No one who knows anything of the history of engineering structures will therefore object to the absence of an abstruse mathematical introduction from Mr. Walmisley's book. His object, as he tells us, "has not been to deal with the methods adopted for the calculation of strains, which have been already well considered by many practical authors in standard works, but to provide a record of the style of design adopted in some of the best-known roofs that have been erected." It must be allowed that so ample a record has not hitherto appeared. Mr. Walmisley has been fortunate in obtaining the privilege to publish the working drawings of about thirty roofs, which are types of different systems. His plates are apparently reproductions on a reduced scale of tracings taken from the originals, and have therefore a style about them that is absent from engravers' copies. The latter might be more pleasing in appearance, but would hardly be equally convincing. A student will, however, find it to be an advantage to colour the sections, and some of the plates will be clearer if a wash of colour is used on other parts as well. The lining is careful, the scales correspond with the figures whenever we have tested them, and generally dimensions are marked on the details. Drawings like those in Mr. Walmisley's book are jealously guarded, and are rarely seen outside the designers' offices. Their publication will be a boon to many. There is a limit to the forms in which plates, bars, and angles can be used, and it is no exaggeration to say that, as this

\* *Iron Roofs, Examples of Design.* Description illustrated with Working Drawings. By Arthur T. Walmisley, C.E. E. & F. N. Spon.

volume shows them all, it thus becomes of more help than the title suggests, and is an exemplification of wrought-iron construction.

The roofs are taken, with one exception, from existing structures in Great Britain, and nearly all belong to railway stations. London supplies those from St. Pancras, Charing Cross, Cannon Street, Blackfriars, Broad Street, King's Cross, London Bridge, Liverpool Street, Earl's Court, and Victoria (two) stations, and the Albert Hall, Aquarium, and Alexandra Palace roofs. The roofs of the four principal stations in Glasgow are given, and Manchester, Liverpool, Leeds, Dublin, Carlisle, Exeter, Bristol, Penzance, Middlesbrough, York, and Swansea are represented. The spans are mainly large, and it would be an advantage if a companion volume dealing with smaller spans were also published. The whole of the illustrations have been reproduced by Messrs. Sprague & Co., and among them are ink-photo views of stations and works in course of construction, which give a better notion of the buildings than is to be derived from drawings.

All roofs may be divided into two classes, viz. (1) those which form triangular trusses, and (2) arched trusses, or, according to Rankine, rafters and arched ribs. The earlier roofs were of the former class, the majority of the more modern roofs are of the latter. The trusses may be braced in an almost infinite variety of ways; Mr. Walmisley assumes that in practice twelve kinds are used—of which five are curved. As examples of the triangular truss have segmental rafters, the proportion of the curves is in practice much greater. The advantage of curved roofs is the width that is practicable. But attempts have been made to secure that end by other arrangements. Thus, for example, at the new Central Station, Glasgow, there are flat girders which are 213 feet 6 inches in length, with a series of small ridge and furrow roofs over them. This roof is, however, hardly so effective in appearance as that in the St. Enoch Station. The main transverse girders of the great Carlisle roof are also flat, the ridge and furrow covering running parallel with them. In this case, however, so much use has been made of circular bracing, that the impression made on a spectator who does not analyse the construction is the preponderance of curves. The roof is simple in arrangement, but to the majority of travellers it is one of the most intricate. The cost, including columns, was only 12*l.* a square. It is glazed on Rendle's system. Two excellent examples in the stations on the Metropolitan District Railway, at Ealing and Earl's Court, also denote that the old-fashioned triangular truss, which is so nearly related to construction in wood, can still be utilised with advantage. But, on the whole, the grandest result is obtainable from curved lines on the principals. In buildings this is especially the case. The Sydenham palace transcends the Hyde Park glass-house in appearance owing to the adoption of arched ribs, and the capital roof of the Winter Palace which formerly stood in Dublin owed much of its success to that cause. The latter was designed by Mr. R. M. Ordish, who appears to be almost the only engineer in England who is capable of imparting an architectural spirit to his ironwork. Indeed, it must be said that the attempts at ornamentation which are recorded in some of Mr. Walmisley's plates are depressing, and suggest how much has yet to be done to bring taste home to the English mind. It is, however, the constructive details that render Mr. Walmisley's book invaluable, and he deserves much credit from the profession for producing so substantial an addition to the Engineers' Library.

### THE ARCHÆOLOGICAL CONGRESS.

THE annual summer congress of the Royal Archæological Institute will be held this year at Newcastle-on-Tyne, during the week from Tuesday, August 5, to Wednesday, August 13 inclusive, under the presidency of the Duke of Northumberland. Tuesday, the 5th, will be devoted to an inspection of the castle and cathedral of Newcastle, after the public reception of the society by the mayor and corporation at the inaugural meeting. On Wednesday the members will visit Warkworth and Alnwick Castles, which will be described by Mr. Clark. On Thursday they will go by train to Beal, from which place Lindisfarne and Holy Island with its church and castle will be visited. Friday will be devoted to a visit by rail to Belford and to Bamburgh Castle. On Saturday the annual meeting of the society will be held. At its conclusion the members will proceed to Jarrow, Monkwearmouth, and, by steamer down the river, to Tynemouth. On Sunday a special service will be held in the cathedral, when it is expected that the Bishop of Newcastle, Dr. Wilberforce, will preach. Monday will be devoted to an inspection of sundry parts of the Roman wall, and to a visit to Chesters, where the Roman remains will be explained by the Rev. J. C. Bruce. On Tuesday the archæologists will go by train to Corbridge, from which they will visit Aydon Castle, Bywell, and Prudhoe Castle. Wednesday will be occupied by a visit to Durham, where the cathedral and castle, and probably Finchall Priory, will be inspected. There will be a meeting on the evening of Tuesday, at which papers will be read, and probably also at least one *conversazione*. A temporary local museum, under Mr. R.

Blair, F.S.A., will be open during the week in the Black Gate, where also the sectional meetings will be held. Among those who have sent their names as patrons of the congress are the Duke of Portland, Lords Ravensworth and Scarborough, the Bishops of Durham, Carlisle, Newcastle, and Hexham, Sir Charles Trevelyan, Sir Joseph Pease, Sir Edward Blackett, Sir Matthew White Ridley, Sir Walter James, &c.

### THE CONSTRUCTION OF HOUSES WITH REGARD TO SANITARY ARRANGEMENTS.\*

BY PROFESSOR T. ROGER SMITH.

THE health of man is greatly influenced by his food, dress, climate, occupations, and dwelling. It is with the conditions affecting the last of these, as they occur in our own country, that we are at present concerned. There are few subjects which are really new, and certainly human dwellings must be nearly as old as the human race. It seems, therefore, reasonable in approaching a consideration of them to cast a glance backwards, and try to see how our forefathers have been housed.

The earliest habitations of which traces remain in England can have afforded little more than a bare shelter from the storm, and some degree of warmth. Yet even those primitive huts, the remains of which are found on Dartmoor and elsewhere, must at least have protected their inmates against the worst vicissitudes of the fickle English climate. It was a fortunate circumstance for ancient Britain that a Roman occupation took place. At such a spot as Silchester you will see the remains of a town regularly planned, and of many buildings of some solidity, decency, and order. What existed at Silchester was repeated in various forms throughout our country, as for example at Colchester, Dorchester, Uriconium. Good methods of building and an orderly mode of laying out dwellings were thus introduced, and to a certain extent took root in the soil.

Every glimpse that we can get of the mode of life of the Saxons, when they became able to attend to the arts of peace, seems to show a largeness of ideas, and an orderly spirit, no doubt greatly due to these Roman traditions and remains. We have proofs, for example, that the Confessor's Monastery at Westminster was planned on the most liberal scale, and very carefully constructed, and so probably were the best Saxon dwelling-houses. The Norman Conquest covered our land with castles and keeps, in the ruins of which good internal arrangements are still to be detected. Such a structure, for example, as the White Tower of the Tower of London, when not overcrowded, must have been an excellent residence, before it became a prison. It is probable, however, that ordinary dwelling-houses, small and large, deteriorated at this time in consequence of the occupation of the land by strangers.

Of English residences built during the Middle Ages, remains have come down to us only from the most strongly built—chiefly the castles. But from the best preserved and most complete of these, as for example Conway Castle, we may learn that the elementary principles of sanitation were understood, and pains and care taken to secure comfort and even luxury, so far as they can be enjoyed within the restricted boundaries of a fortified dwelling; while the semi-fortified houses, of which a few remain in tolerable preservation, such as Penshurst, Ightham, Warwick Castle, and Haddon Hall, were many of them so complete that they continue habitable even by this fastidious generation.

Monastic buildings, from a time long before the Conquest down to the Reformation, afforded a series of admirably well-planned and well-built dwellings for the residence in common of a large number of inmates, the general idea of which survives in the colleges of Oxford and Cambridge. The neighbouring detached but dependent buildings, such as the abbot's house, the mill, and the grange belonging to a monastery, were each and all of them good specimens of small dwelling-houses. They were, however, in all probability, far better than the houses which surrounded them, if we may credit a curious but by no means flattering account of the ordinary English dwelling-house at the close of the Middle Ages which has been lately made public in Brewer's "Henry VIII.," and from which I cannot resist the temptation to quote a few lines. It is from the pen of the most accomplished scholar and cleverest man of letters of the time.

Erasmus, writing to Wolsey's physician on the dwelling-houses of England in the early years of the reign of Henry VIII., says:—"First of all, Englishmen never consider the aspect of their doors and windows; next, their chambers are built in such a way as to admit of no ventilation. Then a great part of the walls of the house is occupied with glass casements, which admit light but exclude the air, and yet they let in the draught through holes and corners. The floors are in general laid with white clay and are covered with rushes, occasionally removed, but so imperfectly that the bottom layer is left undisturbed sometimes for twenty years,

\* A paper read at the conference of the Royal Institute of British Architects at the Health Exhibition on Thursday.

harbouring abominations not to be mentioned. I am confident the island would be much more salubrious if the use of rushes were abandoned, and if the rooms were to be built in such a way as to be exposed to the sky on two or three sides; and all the windows so built as to be opened or closed at once, and so completely closed as not to admit the foul air through chinks, for as it is beneficial to health to admit the air, so is it equally beneficial at times to exclude it."

After the time of the confiscation of Church property, under Henry VIII., a large amount of house-building on a great scale occurred. The vast Elizabethan and Jacobean mansions, of which we are justly proud; and the smaller manor houses, farmhouses, and town houses which were erected at that period, and of which many specimens remain, show a great advance in the art of architecture, and are even now delightful residences.

It is very doubtful whether the influence of Italian and French examples in the seventeenth and eighteenth centuries was not on the whole disadvantageous. Certainly some of the Palladian mansions of about a hundred years ago are less carefully disposed for health, decency, and comfort than the Elizabethan ones which preceded them. The story of what followed, at any rate in the metropolis, will be told us in the paper set down for reading immediately after this, so here my retrospect may well close.

We now live in the era of the steam engine and the railway. An unparalleled revolution, within the lifetime of many of us here present, has changed the social aspect of the country, and has altered the conditions under which our dwelling-houses, especially those in our towns, are built to a remarkable extent. A teeming population of operatives, constantly on the increase, has to be housed somehow; and an enormous number of persons in the middle and higher classes desire, and are able to afford themselves, accommodation of a superior, and in many cases a luxurious, kind. A vast section of our people live in institutions of some sort. The inhabitants of our hospitals, asylums, prisons, work-houses, schools, and almshouses, if all reckoned up, would amount to an astonishing total, and are on the whole well cared for; but scattered over the face of the land our agricultural and mining populations, less affected than the inhabitants of towns by the recent changes, have in many cases to occupy dwellings identical with, or very similar to those of three or four or more generations back.

It is with this state of things that we have to do at the present day. If we try to form an estimate of our actual condition, it will soon become clear that, with our present habits of life, the influence of the dwelling on the health of its inmates is very great. I am inclined to believe that it is much greater than at any previous period. Indoor occupations, for men, are far more common than they used to be, and probably though women have to a large extent lived in the house for several centuries they now do so more than ever. The habits of luxury which increasing wealth brings with it all tend to weaken, or at any rate to refine, our physical organisations, and so render us more and more susceptible to the influences of the material circumstances which immediately surround us. This being the case, it becomes increasingly important that every means should be taken to render dwelling-houses thoroughly healthy.

In one respect the habits of modern life, and the plentiful supply of one of its first necessities, have introduced a very serious danger, the nature and extent of which are happily at last tolerably well known, so that preventive measures can be applied. I allude to the use of water as the vehicle for removing refuse matter from our houses. So many persons imagine that sanitation only means drainage, that I should have liked to pass by the subject entirely, if only to show that other functions of a dwelling as well as the disposal of its sewage are of importance to health. It seemed, however, impossible to avoid this allusion to it. We had unconsciously exposed ourselves to the poison of sewer-gas, and we now find that we must fight tooth and nail to put an end to that danger. Much else is indeed involved in the conditions of healthy dwellings besides drainage, and to much of this the attention of this Conference will be directed by the papers about to be read and discussed.

Good disposition of the houses in a town, a street, or even a small group, so as to secure the best aspects and the largest amount of sunshine, air, and clear space, is a matter of primary importance, the more so because pecuniary interests often appear adverse to the best sanitary conditions. Good disposition of the plan of the dwelling itself is of the utmost importance from a sanitary point of view; but its value is, I think, more recognised by the public, and even by speculative builders, than the importance of healthy laying out of sites for houses.

Adequate ventilation, including methods for the removal of vitiated air from gas burnt in our dwellings; sufficient means of warming; ample windows, properly placed to light the whole of each room; sound construction, so as not only to make the dwelling desirable, but to protect the inmates from the effect of inclement weather, especially of cold and of damp, those greatest enemies to health and comfort in this country; protection from noxious compounds in the paint or paperhangings used for the dwelling; complete systems of drainage and of ventilation for the drains; and an ample supply of pure water, hot and cold, are

among the obvious features of house sanitation. Other less obvious matters remain. The influence of monotony, of insufficient light, of dulness, is known and felt by us all as depressing, or, in other words, as unhealthy; and the designer of a dwelling which is to be fit to be a home should have in his mind the necessity for its being pleasant quite as distinctly as the more obvious questions of where to put his drains, or cisterns, or stoves.

I propose to conclude by directing your attention for a moment to a consideration with regard to which something may be said, without, I hope, anticipating what we are to hear from others. I refer to the share which the architect may properly claim in the duty and privilege of promoting public health by improving the construction of dwellings. In other words, I propose to ask how far all this is an architect's question.

It is not sufficiently known to the general public, but well known to ourselves, that the actual direct control possessed by architects over the majority of the dwelling-houses built in England is extremely small. When Prince Albert wanted to improve Buckingham Palace he sent for Thomas Cubitt, builder, and contrived it with him without professional advice; and this is the kind of thing which has been done by other persons less highly placed since then. In ninety-nine cases out of a hundred, the dweller in or near one of our towns, especially this metropolis, never dreams of building his own house, and looks out for one ready built by a speculator, and puts up with untold inconveniences, and even dangers, from its many defects. But notwithstanding all this, the opportunities which we possess of influencing the buildings of this country are very great; they are such as no other body of men enjoys. We can do a great deal to secure that the homes of England are healthy; and if we fail to do all that we can, we shall be failing in a great public duty.

In the first place, I think it may be safely affirmed that whatever may be the case in towns, the country house of a person of influence and importance is now never built without an architect. From parsonage houses upwards we have the designing and superintendence of all the houses of the clergy in their parishes, and the rich when they are living on the estates. These, then, we can make as fit to promote health and to avert disease as we are able, and they ought to be as healthy as any buildings can be. Collectively they provide for a vast number of residents, including a great proportion of the most important men and women of the country; and, in addition to this, they are conspicuous as models. The dwellings of the highly-placed should be perfect, not only for their own sake, but because such buildings are sure to be imitated, and their owners are most likely to promote sanitation when their own dwellings teach them what it means. What persons of power and influence do, others in lower positions in life will endeavour also to do, and what they recommend will be likely to be followed. In not a few cases such persons are themselves builders of labourers' dwellings, while among them are some whose estates situated in London are each of them equal to a populous city, within which the owner of the soil has it in his power to prescribe any conditions he pleases to the persons who build or rebuild houses.

Next perhaps in importance from our present point of view are our countless residential institutions, if that term may be used to denote public buildings where persons live temporarily or otherwise. Every college, school, hospital, workhouse, &c., has its architect, and we have even seen military barracks erected by civil architects. The very purpose of these buildings renders attention to their sanitation one of the most positive duties of the architect.

At the other end of the scale the very numerous model dwellings erected in London and other cities for the urban labouring population, and not a few agricultural labourers' dwellings, are almost always put into the hands of architects, and are buildings in which sanitary excellence is often the only good quality that the architect has an opportunity to impart. Between these two extremes lie the numerous dwellings of the middle class, which, as has been said, are far less under an architect's control than the buildings above or below them; yet it must not be forgotten that from time to time an individual house is commissioned, and ought to become a model. Some of the most intelligent of the building speculators are occasionally wise enough to employ an architect of skill and repute and to build from his designs, though hardly perhaps under his direction. In all such cases the architect should be sure that not only the ordinary appliances of sanitation, but, as far as possible, all the finer elements of a healthy dwelling, are present in his design, and should bargain that they are retained. Even in the case of the vast melancholy multitude of ordinary dwellings built by speculators on leasehold ground, there is one period in their history when an architect exercises some considerable control, and when, if he is thoroughly familiar with what makes houses healthy, he may prescribe and enforce building conditions that shall greatly benefit future occupiers. But nothing will effect a great improvement in these dwellings except a radical change in public opinion and feeling on the subject, and it may be hoped that such a Health Exhibition as this will tend to foster such an instructed public opinion.

It will, I trust, be conceded that the health of the community is one of the most important elements of its well-doing, and further that the dwelling may very largely impair or improve that health

according as it is bad or good. I trust I have shown sufficient reasons for our recognising that this is pre-eminently an architect's question, and, if that be admitted to be the case, it will hardly be necessary for me to bespeak your best attention to those of our professional brethren who are to address us on some of the details of the subject, and ask you to contribute to its elucidation by joining with spirit in the discussions.

### YORKSHIRE CHURCHES.

THE members of Lincoln Diocesan and Yorkshire Architectural Societies on the 3rd and 4th inst. visited the churches in Hull and district. Service was held in Holy Trinity Church on the morning of Thursday, after which the architectural features of the fabric were described by the Rev. Canon McCormick. The old Hull Grammar School was also visited. The societies were received at the Town Hall shortly before ten o'clock by the Mayor (Dr. Rollit), and carriages started thence to Hedon, Preston, Keyingham, Ottringham, Patrington, and Halsham. Alderman Park, of Hedon, gave a very interesting description of the exterior and interior of the parish church of Hedon, which town, it may be stated, is an old Parliamentary borough, and was disfranchised by the Reform Bill of 1832. The Patrington parish church was described by Mr. F. S. Brodrick, architect, of Hull. Ottringham Church was described by Mr. Brodrick, from a paper prepared by Mr. Fowler, architect, Hull. This church dates its origin from the fifteenth century. The Bishop of Nottingham made some critical remarks on the old Norman church of Halsham, the principal attraction at which was a freedstool or sanctuary chair, which the party inspected with great interest, as it had hitherto been believed that there were only two in existence in England, viz., those at Beverley and Hexam. Here there is also a recumbent statue in armour, supposed to represent one of the Constables of Burton Constable. The spire at Keyingham Church is of solid stone. Other places of interest were visited during the afternoon.

The proceedings on the second day began with a visit to St. Mary's Church, Hull, which was described by the Rev. Canon Scott, the late Vicar, but now of Leeds. A special train conveyed the members to Beverley, where the Minster was visited. A good paper was read by Mr. F. S. Brodrick, who afterwards conducted the party round the Minster. Mr. W. Stephenson, of Beverley, described the well, and some objects of archaeological interest found in it. The church of St. Mary and the North Bar were also inspected. The party next went by train to Bridlington, where the Priory church of St. Mary was described by Mr. J. Fowler. The Bayle gate was likewise inspected. Burton Agnes was then visited, where, by the permission of Sir H. S. Boynton, Bart., the party were shown over the hall. The return to Hull was made in the evening, and a public meeting was held at the Town Hall at 8.15. The programme in the evening included the reading of a paper by Precentor Venables, on "St. John of Beverley: his Miracles and his Ministry;" and one by Alderman Symons, M.R.I.A., on "Hull in the Olden Times."

### THE WINCHESTER CELEBRATION.

THE celebration of the seven-hundredth anniversary of the foundation of the mayoralty has been held in Winchester, and with great spirit. There was a special service in the cathedral, which was attended by a great many visitors, representing the corporations of London and other towns.

The Dean, in his address, spoke of the antiquity of the cathedral, and said that forty years ago they might have celebrated the twelve-hundredth anniversary of the founding of that church, large portions of which of the most imposing and splendid character were standing a hundred years before the day they had met to celebrate. Remarking upon the change in the character of English architecture, which, as exemplified in this cathedral, began about the time the charter for the mayor and corporation was granted, the new style shaking itself free from the Norman influence, he observed, that in a similar manner the civic mayoralties of England, of which that of Winchester was the first, became places in which the tyranny of the Norman conquerors could be withstood and overcome. The great grievance under which the English people in the twelfth century suffered was not the oppression of their kings, but of the Norman feudal nobility. Those early cities were fortresses in which the people of the land could take refuge in those terrible times, and they received the greatest encouragement and support from those who, quite as much as the native portion of the English people, hated the Norman masters of the kingdom. This, he ventured to say, was why the great King Henry II. set the new movement on foot by this first charter. They were there to celebrate the birthday of the unifying act by which the group of all but independent societies or guilds in an English city hitherto presided over by a portreeve or sheriff, were brought into one great city under a mayor and corporation. Henry II., as it had been suggested, wishing to signalise the birth of his German grandson, who was born in Winchester, created an epoch in English muni-

cipal history. He was half a foreigner, his possessions in France were larger even than those of the Kings of France, and it was not wonderful that he should look there for some means whereby he might strengthen the good city of Winchester, and in the towns of France he would see that they had lately introduced an officer who was called *Le Marre de la Ville*, and who was, as the name indicated, the head man of the town. Thus we had arrived at a true municipal constitution, and in the first mayor of Winchester we found the first example of a civil power able to withstand all bad government, tyranny, and oppression whatsoever. Tracing the corresponding growth of municipal institutions in Germany in the towns of the Hanseatic League, he remarked with regret upon signs to be found, as in Lubeck, of the bitterness of the struggle which took place between the municipal and clerical powers for supremacy. Referring to customs which formerly prevailed in Winchester when the great fair of St. Giles was held, and the bishop of the diocese for sixteen days held the keys of the city and placed his own officers at the gates to take toll of all comers, he observed that he was not aware, however, that there had ever been any serious differences between the bishops and the people of the city.

The commemoration committee subsequently entertained their visitors at a luncheon in the County Hall.

Mr. Melville Portal, to whose exertions are mainly due the restoration of the ancient castle hall, or great banqueting-hall of the Royal Palace, dating from the time of Henry III., where the luncheon was served, proposed the toast of "Prosperity to the City of Winchester." He said that no one could look around that noble hall without his heart being stirred within him. Every stone in the building was bristling with memories of the past, and had a history connected with the greatest events of this great kingdom, and who could look round on that occasion without feeling moved at the sight? That great multitude had met together determined to connect the great past with the present—to commemorate an event of seven hundred years ago, and their presence seemed to him a most interesting instance of the great congruity of the country. Sitting at that table imagination might almost cause them to listen for the re-echo of the voices which they knew caused the hall to ring in times past, where such men made their mark as Wykeham, Waynflete, Gardiner, and Fox, Raleigh and Walsingham, Coke and Jeffries, Andrews, and many others, who in their several ways had made an impression upon the country, from which every one present, more or less, benefited. They were met again in that great hall, after it had been empty for centuries—not met as their ancestors did to scheme plans of war, they were not even met for the purposes of State, but peacefully to commemorate the success of that institution which their ancestors saw in its cradle, and which they had, by the blessing of Providence, lived to see in its maturity on its seven-hundredth birthday. There had been banquets before in that hall—banquets of a more sumptuous character probably, notably that given by the Fifth Henry to the ambassadors of Charles of France, and by Henry VIII. to the Emperor Charles of Germany and Spain. It was possible that had Henry VII. been there that day he might not have preferred the band the mayor had provided for their entertainment to the miracle plays. Those banquets may all have been grander and more gorgeous, but there never was an occasion when a banquet was more worthily and peacefully held than at the present, for they were met to celebrate the anniversary of a great institution, of the greatest importance not only to the city but the kingdom at large—an institution far older than the House of Commons itself, and which was the origin of self-government in this country, which was the nursery of that manliness and independence of character which was the characteristic of the English people.

The Mayor of Winchester thanked Mr. Melville Portal and the Right Hon. G. Sclater Booth for the use of that hall, without which it would have been almost impossible to have celebrated the event. That hall was once the property of the citizens. In 1656 the Corporation purchased the hall and its surroundings for 260*l.*, but in 1682 the citizens showed their great loyalty by giving it back to the king for nothing at all. He thanked the committee for the assistance they had rendered him, and particularly to Mr. H. Wyeth and Mr. White. He also thanked the mayors for their attendance, and hoped Mr. Portal's history of that hall would be published concurrently with the new work in connection with the city of Winchester, and if that celebration produced only those two works, and led to the recovery of their ancient charters, it would not have been held in vain.

In the evening there was a torch-light procession, in which a series of *tableaux vivants* were carried through the principal streets. The histories selected were Henry II. granting a charter to Winchester, Richard II. giving a charter of incorporation for the college to William of Wykeham, the visit of Henry VI. to the shrine of St. Swithin in the cathedral, Charles I. brought a prisoner to Winchester in 1648, Cromwellian soldiers searching for Royalists, Sir Christopher Wren presenting his plans for a royal palace at Winchester to Charles II. The tableaux were mounted on platforms, which were fixed on trolleys. A memorial of the commemoration has been produced at the expense of the Mayor, Mr. Stopher. It is a medal which on the obverse has a

reproduction of the seal of Edward I., given to the city in 1276, and on the reverse the legend—"To commemorate the 700th anniversary of the Mayoralty of Winchester."

### HOSPITAL PLANNING.

A MEETING of the Birmingham and Midland Association of Medical Officers of Health was held on the 3rd inst., when a paper on "Hospitals for the Isolation and Treatment of Infectious Diseases" was read by Mr. George Wilson. The author said that, in order to stamp out infectious diseases in large towns and populous districts, sanitary authorities must provide adequate means for isolation and treatment, and such hospital accommodation must be open to all, and free from the stigma of pauperism. He was strongly of opinion that where such hospital accommodation was provided there would be no general insistence on payment, and especially when such cases were removed by order or with the approval of the medical officer of health. Unfortunately, the question of hospital accommodation as a means of sanitary defence was even yet but slowly recognised, and seldom entertained at all unless under the pressure of a severe epidemic. It was the duty of every urban sanitary authority at least to provide hospital accommodation for the reception of dangerous infectious cases, and even for small towns the minimum amount of accommodation should be sufficient for the reception of cases of both sexes suffering from two different kinds of infectious disease. In other words, there should be two separate blocks, each consisting of two separate wards and a nurses' room, and with an administrative block between. There was a small hospital of this kind at Solihull Union, which had done excellent service. Tents could only be regarded as makeshifts, and he felt sure that no sanitary inspector would advise his Authority to rely upon them as affording adequate accommodation for future outbreaks. For small districts he recommended that movable iron hospitals would be found more serviceable and cheaper in the long run than any other. Having referred to the difficulty of selecting sites, he spoke of the number of beds which should be provided. In manufacturing towns it was estimated that one bed for every 1,000 of the population should be provided, but for suburban districts he should think one in 1,500 would be sufficient. For nursing purposes he did not think that any single ward should contain more than twelve beds, and in permanent buildings each bed should be allowed a cubic space of at least 2,000 feet. Large hospitals should consist of pavilions in double echelon, as recommended in the circular of the Local Government Board. There was no reason why some of the pavilions should not be two-storeyed. For a hospital containing twenty beds, and consisting of two pavilions, administrative block, and outside offices, he was of opinion that the whole could be erected for 3,000*l.*, or about 150*l.* per bed.

### Arsenical Pigments in Mural Decoration.

SIR,—In your issue of June 21 Messrs. Woollams & Co. have been good enough to notice the abstract from my lecture given before the Leeds and Yorkshire Architectural Society. I regret that my attention has only just been directed to their remarks. Messrs. Woollams are inclined to question my assertion that "the size with which the colours are mixed before printing" wall-papers are—or have been—at times "impregnated with arsenic, added on account of its antiseptic properties." This statement was made upon what I considered the highest authority, from information kindly given to me some time ago by a manufacturer, and also more recently repeated by a second; but, as the head of the firm who afforded it is now abroad, I am unable to obtain his sanction to the publication of his name. My expression that "the size . . . used to be impregnated with arsenic," and that this addition is now rendered "unnecessary," should be sufficient to set at rest any uneasiness on the part of the public, if any there be.

I have also been privately reminded of the case "Steinhoff v. Woollams," which shows that paper manufacturers may still become the victims of the Imperial order which permits German makers to export colours containing arsenic. Why should not such vendors be compelled to declare upon sale whether their goods are free from arsenic or not? It is apparently impossible for the English manufacturer invariably to protect himself by private analysis only.

Messrs. Woollams in their letter also refer to my case of death from supposed poisoning with a wall-wash, which proved to be intensely arsenical. This case occurred in 1879, and was reported to the Committee of the Medical Society of London, but after their report (February 1880) was published. The excretions of my patient were most carefully analysed by Dr. Thorpe, F.R.S.,

Professor of Chemistry to the Yorkshire College, and by Mr. Bothamley, F.C.S., his Assistant-Lecturer, whose names are sufficient guarantee that all impurity of reagents employed was rigidly guarded against. The process employed was that of Fresenius and Von Babo—a most delicate one, in which no copper is used. This is not the place for the discussion of medical details, but perhaps I may be allowed to quote from Professor Thorpe's report, which runs as follows:—"Arsenic is present in both the urine and the fæces. The amount in both cases is extremely minute—far too small to admit of quantitative estimation—but the quantity of the arsenic film yielded by the fæces was unmistakably larger than that afforded by the urine." These excretions were only collected the day before the man died, and *six weeks* after he had been removed from the sitting-room where the poisonous wash existed. It is unfortunate that Dr. Allbutt and I had not sooner become alive to what we assumed, in the absence of other cause, to be at the root of the fatal malady. Had a post-mortem examination been allowed, we should probably have had no difficulty in detecting arsenic in large quantities in the internal organs, where it is well-known that it is often retained for a considerable time after entering the body.

I would merely add that my lecture was given from short notes, and the published abstract afterwards written in a condensed form—hence the absence of any detailed description of my cases.

I am Sir, faithfully yours,  
CHAS. J. WRIGHT.

Leeds: July 8, 1884.

### LEGAL.

#### High Court of Justice, Queen's Bench Division.—July 8.

(Before Mr. BARON HUDDLESTON.)

BLACK v. HAMMOND.

This was a case transferred from the Chancery Division, in which the plaintiff, Mr. William Black, the novelist, sought for an injunction restraining the defendant from erecting any building whatever on a small piece of land separating his (Mr. Black's) house from that belonging to Mr. Hammond. The person from whom the latter derived his title had entered into a covenant not to build on the piece of land in question, which was less than 300 square feet, and for which as much as 630*l.* had been paid, in such a way as to injure Paston House, Mr. Black's house, or to lessen its value. The plaintiff contended that by this covenant the defendant was prevented from erecting any building of any kind on the spot in question, but the defendant's contention was that the covenant was only a qualified one, and did no more than prevent his erecting anything there that would diminish the value of Paston House.

Mr. Baron Huddleston, in giving judgment, observed on the conflict of the evidence in the case as to the time at which a hoarding had been put up on the piece of land in question, which the witnesses for the plaintiff said had been erected in 1879, while those called by the defendant said it had been put up in 1870. If he rejected the positive evidence of the latter he should have to say that they had, in his opinion, been guilty of perjury. Happily he should not have to say that he disbelieved their testimony, and in taking this view he should not have to hold that the plaintiff's witnesses had said that which to their knowledge had been untrue. The evidence of the latter was much less direct, and, so far as it contradicted that of the defendant's witnesses, might well be considered to be the result of a mistaken view of facts which had occurred many years ago. The plaintiff was not entitled to the injunction for which he asked, nor to any damages, as his property had not been lessened in value by anything that the defendant had as yet done. The action, therefore, would be dismissed with costs.

(Before Mr. JUSTICE FIELD.)

TOMLINSON v. BURNETT.

The plaintiff in this case was an architect living at 35 Great James's Street, W.C., and the action was brought to recover fees amounting to 167*l.* 7*s.* for preparing plans for houses at Sutherland Gardens, and for the extra supervision which was requisite in consequence of the builder failing to carry out the contract. The defendant had a counter-claim of 2,000*l.* for alleged negligence, and by order had previously paid into Court 100*l.*, besides the sum of 27*l.* 10*s.* obtained by the plaintiff on account. It was agreed that the plaintiff was entitled to the sum of 91*l.* 7*s.* for plans, &c., and a fair sum for extra supervision from the time of the builders leaving the works until completion. Mr. Henry Hunt was appointed referee. The evidence showed that the plaintiff had been put to considerable annoyance, having been held responsible by several firms for goods supplied for the defendant's houses. Mr. Hunt reported that the plaintiff was entitled to the sum of 26*l.* 5*s.* for extra services, and that the defendant was not entitled to anything on his counter-claim. His Lordship entered judgment for the plaintiff, with full costs, accordingly.

The surveyors engaged on the side of the plaintiff were Mr. W. H. Haynes, A.R.I.B.A., and Mr. Robert Dixon, and Mr. Thicke for the defendant.

## WORKS IN PROGRESS.

**Messrs. Boyle & Son**, of Holborn Viaduct and Glasgow, are applying their system of ventilation to the new workhouse, Wandsworth. The air-pump ventilators will be affixed to the top of specially constructed air flues, which are carried above the roof of the building. The fresh air is admitted by Messrs. Boyle's improved inlet brackets. It is believed that when the work is completed, it will prove to be one of the most complete and successful systems of ventilation which has yet been applied to any public building.

**Messrs. Archibald Smith & Stevens**, of Janus Works, Queen's Road, Battersea, have received orders from the contractors, Messrs. Perry & Co., to put in one of Stevens & Major's patent hydraulic suspended lifts at the Queen's Mansions, Victoria Street, Westminster. The travel of the lift will be 76 feet.

**Messrs. J. Waygood & Co.**, of Falmouth Road, S.E., have received orders from the contractors, Messrs. Perry & Co., to supply and fix one of their hydraulic multiplying lifts at Prince's Mansions, Victoria Street. The travel of the lift will be 80 feet.

**Royal Agricultural Show, Shrewsbury.**—"Norton's" patent "Abyssinian" tube-well system has been adopted for the entire water supply of the grounds. Messrs. Le Grand & Sutcliff, hydraulic engineers, London, have furnished eight of these tube wells, 3 inches diameter, which are connected to one 5-inch cast-iron horizontal main. A central outlet from this main leads to a steam pump, which delivers a supply of 15,000 gallons per hour of clear, pure water, such as is seldom obtained at these meetings. The "Abyssinian" tube wells are not unknown in Shrewsbury, as a few years back Messrs. Le Grand & Sutcliff laid down a supply of 30,000 gallons per hour on this system for the Corporation Waterworks.

**Ebbesborne Wake, near Salisbury.**—A new treble and new tenor are to be added to the existing ring of three, making a ring of five, and a new frame and fittings for the whole. The work has been entrusted to Messrs. Llewellyns & James, Bristol.

## CHURCH BUILDING AND RESTORATION.

**South Elmsall, near Doncaster.**—The foundation-stone of a new Wesleyan church in this village was laid on Thursday, June 19. The buildings are of Elland flagstone, with sandstone dressings and Ancaster for the interior. The woodwork is of pitch pine and English oak. The church gives accommodation for 350 persons. There are two vestries in the rear. The entrance to church is through tower, above which rises a slate spire to 90 feet. The works are being carried out, at a cost of 1,500*l.*, from the designs of Mr. James Wilson, architect, of Leeds.

**Birmingham.**—The memorial-stones of the Asbury Memorial Wesleyan chapel, Handsworth, have been laid. The chapel is Early English in style, and will be built of brick, with stone dressings. Internally the chapel has a centre aisle and side aisles, and will accommodate about 600 worshippers. The roof is to be of stained pitch pine, and the seats of pitch pine, and the floor will be composed of wood blocks. The cost of the edifice will be about 4,000*l.*, and it is being built by Mr. J. Bowen, of Balsall Heath, from the plans of Mr. Ball, architect, of Corporation Street, Birmingham.

**Steeple.**—The new church dedicated to St. Lawrence and All Saints has been opened. The cost of the building has been about 2,000*l.*, and it has been erected by Mr. Letch, of Braintree, from the designs of Mr. Fred Chancellor, of Chelmsford.

**Derby.**—The first sod in the excavations preparatory to the erection of a permanent church for the outlying district of St. John has been cut. Plans have been prepared by Mr. A. Coke Hill, and the contract has been let to Messrs. Walker & Slater.

**Heaton.**—The design of Messrs. S. Oswald & Son, architects, of Newcastle-on-Tyne, has been selected in limited competition for a new Wesleyan chapel at Heaton. The buildings comprise a chapel with 900 to 1,000 sittings, a lecture hall for 350, and five class-rooms and vestries. The design is in the early Gothic style, with tower nearly 90 feet high, at the corner of Heaton and Tyne-mouth Roads.

**Balerno.**—A new United Presbyterian church has been erected in Balerno, from designs by Mr. James Fairley, of Edinburgh. The contractors are:—Messrs. Turner, Juniper Green, mason; Fairbairn, Balerno, joiner; Nisbet, Juniper Green, plumber; Anderson, Edinburgh, slater; and McDonald, Edinburgh, plasterer.

**Meltham.**—The memorial-stones of a Wesleyan chapel have been laid. The building will be in the Classic style of architecture, and will provide total accommodation for about 800. The outside walls will be of pitch-faced rocks with ashlar dressings. The contractors are:—Masons, Messrs. E. Pogson & Sons; joiners, Messrs. Garlick Bros.; painters, Messrs. J. Preston & Sons; slaters, Messrs. W. Goodwin & Sons; plumber and glazier, Mr. George Garton; plasterer, Mr. Geo. Jackman; and the architect is Mr. Joseph Shaw, Holmfirth.

**Warwick.**—A chapel erected by public subscription, at a cost of over 700*l.*, has been opened at the workhouse. The building is capable of accommodating some 250 persons, and has been erected from plans prepared by Mr. F. H. Moore, architect, Warwick; the contractor being Mr. Thomas Bailey, builder, &c., Leamington. It consists of nave, chancel, and porch, and is built of ordinary pressed red brick of the district, with Bath stone copings, window-heads, and dressings.

## GENERAL.

**The Marquis of Bute** has given permission to art students and others to copy the pictures in the Bute collection now exhibiting in the Corporation Galleries, Glasgow.

**The Aberdeen Art Gallery** has obtained through bequest a valuable collection of paintings belonging to the late Captain Gordon of Fyvie. Mr. Macdonald has also offered to present to the museum a large granite figure from a design prepared by Mr. Lawson, sculptor, London. To these gifts are to be added the sculptured head of Minerva, presented by Sir John Steele, which now forms the keystone of the archway over the main entrance to the building.

**The Liverpool Reform Club** has been decorated according to designs by Mr. Edmund Kirby, architect.

**The Estimates** for the new town hall, at Hawick, amount to over 8,500*l.*, exclusive of architect's fees, painting, and other expenses, which will increase the cost to over 10,000*l.* The sum that was fixed in the instructions to competitors was 5,000*l.*

**The Design** of Messrs. S. Oswald & Son, of Newcastle, has been selected in limited competition for a new Wesleyan chapel to be erected at Heaton. The chapel will seat 900 to 1,000 persons, and adjoining it there will be a lecture hall for 350, besides five class-rooms and vestries. The style adopted is Early English.

**Mr. W. H. Weatherill**, of Stockton-on-Tees, has been appointed architect for the new Board schools in Tilery Road in that town.

**The Foundation-stone of the New Putney Bridge** will be laid to-day (Saturday) by the Prince of Wales. The bridge is to be of masonry, having five elliptical arches, and is constructed by order of the Metropolitan Board of Works. Models and plans of the structure will be exhibited to the Prince and Princess of Wales.

**Residential Flats, West Brighton.**—We have been asked to state that the design for Mr. Chappell's new buildings was prepared in his office by Mr. Stark.

**The Old House** in Middle Scotland Yard, which, since the year 1820 has been used as the Royal Almonry, is about to be pulled down to clear the ground for some new buildings, which are to be erected on the vacant land belonging to the Crown in its immediate vicinity.

**Mr. Gustav Bishop** has obtained a prolongation for seven years of his patent for filters, in which spongy iron is used as the purifying medium.

**The Lord Mayor**, supported by Sir James Lawrence, Lord Reay, Mr. Alderman de Keyser, Mr. P. L. Simmonds, and an influential company, lately distributed the medals awarded to successful competitors at the recent Amsterdam International Exhibition. Mr. H. C. Stephens, the ink and wood stain manufacturer, of Aldersgate Street, received no less than three gold medals for his useful productions.

**A Builder**, living in Highgate, has been fined 8*l.* and 2*l.* 2*s.* costs for having covered in the drains and foundation of a house erected by him near Lichfield Grove, Finchley, without giving notice to the surveyor of the Board of his intention to do so, and further, for having refused to lay open certain specified work for the inspection of the surveyor.

**The Proposed Wallace Statue.**—Upwards of twenty designs have been received in Aberdeen from British and foreign sculptors. They have been unpacked and deposited in the Joint Hall in the Municipal Buildings, but will remain covered till Mr. Steill's trustees and their assessors, Sir Noel Paton and Dr. Rowand Anderson, have adjudicated on them. These gentlemen are expected to meet in Aberdeen with the view of settling on the design to be adopted, and that to which the premium of fifty guineas shall be awarded as next in order of merit. A desire has been expressed that arrangements be made for exhibiting all the designs to the public during a limited period after the adjudication.

**Messrs. Robert Boyle & Son's Patent Self-Acting Air-pump Ventilators** have just been applied by the Admiralty to the whole of the drainage system at Sheerness Dockyard. Messrs. Boyle have also recently applied their system of ventilation to the General Post Office, Liverpool; General Post Office, Leeds; Grand Hotel de Grasse, Alpes Maritimes; Albert Memorial Museum, Exeter; Brixton Town Hall; Rochdale Free Library, Rochdale; New Public Baths, Forest Hill; and the Convent of the Good Shepherd, Hammersmith.

# SUPPLEMENT

TO THE

# ARCHITECT.

CHILMARK AND WARDOUR STONE QUARRIES,  
WILTSHIRE.

**STONE.—PORTLAND SERIES,** of which  
Salisbury Cathedral is built; also used in the restoration of  
Westminster Abbey and Chapter House, Chichester and Rochester  
Cathedrals, St. Albans Abbey, many Churches, Mansions, &c.  
Price of Block, Sawn or Worked Stone, Steps, Paving, Walling  
Stone, Rough Blocks for Engineering Purposes, &c., on applica-  
tion to T. F. LILLY, Gillingham, Dorset.

**READING CASES FOR THE ARCHITECT**  
Price 2s.—Office: 175 Strand, London.

**W. H. LINDSAY & CO.,**

PADDINGTON IRON WORKS, LONDON, W.,

AND SANDYMOUNT FOUNDRY, LLANELLY, CARMARTHEN.

**PATENT WROUGHT-IRON SASHES AND WROUGHT BOSSES**

SPECIALLY ADAPTED FOR WAREHOUSES, SCHOOLS, AND PUBLIC BUILDINGS.

CABLE LIGHT

The Patentee begs to call particular attention to the great strength of this construction. The Bars and Bosses, being of malleable wrought iron, form an exceedingly firm joint at the intersection of bars. They are durable, and of light appearance, the Bosses being small and not unsightly. They can be made at very short notice, and at the price of an ordinary cast iron sash.

PRICES UPON APPLICATION.

CABLE LIGHT.

CLOSE BAR SASH (obviating use of Window Guards).

ORDINARY WAREHOUSE AND SCHOOL SASHES.

VENTILATOR

Back view of Boss, full size.

Section through Boss, full size.  
These can be glazed flat, like ordinary wooden sashes, without the corners of the panes being chipped off.

Front view of Boss, full size.  
Obscuring no appreciable light.

**REPRINT of ART PLATES from "THE ARCHITECT."**

There are now on Sale a few Sets of the

**SHAKSPERIAN DECORATIVE PANELS**

By H. STACY MARKS, R.A.

**PRINTED IN COLOURS.**

Price Five Shillings the set of Eight; or free by post, carefully rolled, Five Shillings and Sixpence.

# The Architect.

## FALSE ECONOMY IN BUILDING.

CURIOUS illustration of one of the weakest points in the practice of modern building was afforded at the Conference which was conducted under the administration of a committee of the Institute of Architects at the Health Exhibition last week. Thirty or forty short papers and speeches in the interest of wholesome building were delivered at the three sittings which were held; almost all of them came from professional architects; the range of subjects was considerable, from the smell of drains and the smoking

of chimneys to the artistic effect of colour decoration and the enjoyment of flowers; and it was singularly noticeable that scarcely a question of any moment was raised without its being made to turn upon considerations of expense. Either the proposer of an improvement took pains to deprecate criticism by arguing that it would not be expensive, or his critics took for their weightiest objection the apprehension that it would be so. As a rule, the supposition that anything could cost nothing at all was regarded as a mathematical impossibility, and the simplest hint that it would cost a good deal was taken for an insurmountable obstacle. The best policy was to admit that it would cost something and apologise for it. All this, we say, formed a remarkable illustration of a certain parsimonious instinct of modern English architects which ought to be seen to.

Why it should be so we do not for the present inquire; but it must for a long time have impressed most people of liberal intelligence that the typical British architect, who is one of the most timid of men in all things, is so particularly timid about money matters as to hamper his action materially. A little story is told of a gentleman who some twenty years ago was in the front rank of the metropolitan profession. On one occasion a client, having had certain plans explained to him, and being exceedingly pleased with the successful way in which they fulfilled his instructions, inquired at last what would be the cost. The cost, said the architect, *without* the deprecatory expressions that are customary, would be so much. "Indeed?" was the rejoinder, "that is a large sum of money." Said the architect calmly, "That's your affair, not mine." Most architects of the present day will be disposed to doubt the truth of such an audacious anecdote. It would have been much more in accordance, we need scarcely say, with everyday usage, if the observation about the large sum of money had been humbly taken as a personal rebuke, to be answered rather by meek confessions of regret, entreaties to be permitted "to try whether some reduction cannot be made," and, possibly in some cases, by declarations, more respectful than self-respecting, that no one else can do things cheaper.

A cheap building, like a cheap coat, is an essential mistake. Good value for the money is another thing; but a market price cut down to the lowest figure, whether with the builder or the tailor, means scamped materials and scamped workmanship, and cannot mean anything else. And the fact is—strange as it may seem—that the straining after cheapness in building is not the act of the public, but the folly of architects. Indeed, to such an extent is this folly now carried, that, even when leading architects meet as they did last week, in the very face of the public, to discuss the urgent necessity for making the dwelling-houses of the better classes of English people healthy instead of unhealthy, they seem to regard it as a condition preliminarily imposed in the very nature of things, that if the improvement is to cost anything the proposal cannot be entertained! It is enough to say that in such an absurd mode of dealing with such a question the public cannot possibly be imagined to sympathise; and we do not hesitate to go further, and affirm that in nothing whatever that is matter of building, either public or private, is such sympathy really existant. It is foolish architects, we repeat, who persuade people to a parsimony for which there is no need, and which results only in dissatisfaction, and frequently disaster, to all concerned.

No one, of course, will pretend to suppose that all our architects are alike parsimonious. The best, and indeed the shortest, road to professional success and esteem is to practise liberality, and many of them quite understand this. Nevertheless, not only is it the fact that many others proceed upon the contrary principle—that to have a reputation for cheapness secures business—but even the best men are often far too ready to forget that a well-to-do Englishman, when he is spending his money so freely upon the best of everything else, is at least equally desirous of having his house, or his warehouse, or his church, of the same superior quality. That he should have fair value for his outlay, as has already been said, is no doubt his very rational desire, but that the quality should ever be sacrificed is not his desire. The liberality of his expenditure with a builder—often a very flourishing builder in consequence—when there is no architect employed, is of itself a notable proof of this; and his bills for furniture and ornaments, even when he prudently keeps at a distance from CHRISTIE'S, and perhaps refuses on the threshold all temptations to become a "collector" of even the most modest things, are almost more signally so.

To hark back a long way—or in some instances not so long a way after all—let us think for a moment of those architectural works of historical character, which in all the chief seats of culture have been recognised as being amongst the proudest insignia of civilisation. The maxim of a very respectable London architect, which we quoted a short time ago on the occasion of his decease—"to build, not merely strong, but stronger than strong"—is easily understood in its practical application; and may it not be truly said that it is the acceptance of this rule that has given permanence to almost every one of these edifices? To pass over the massive structures of more remote antiquity, where are the Mediæval and Renaissance buildings now which happened to be not built "stronger than strong?" In our own times the science of what is called economy—if the term science had not better be exchanged for some other word—seems to be based upon some simple notion that the "stronger than strong" is in principle a fraud upon the pocket of the proprietor, by which the designer derives a personal profit, to the extent, it is true, of only a shilling in the pound, but so much the worse.

The idea may occur to some readers that the desire "to keep down the expense"—a phrase employed most earnestly by architects all over England every day in the year—has its origin in the consciousness that so much of the detail of academical architecture consists in characteristic ornament of various kinds which the uninitiated do not appreciate, and of which the designer himself, so to speak, derives the sole benefit. So far as any feeling of this kind is actually entertained, either by the architect or by his employer, however vaguely, or even under whatever disguise, it is easy to see that a certain sense of awkwardness must creep into their relations with each other. Probably there are few of us, if any, who are philosophical enough as yet to recognise how much of our designing, if weighed in the strict balance of æsthetic virtue, would be found wanting. The late OWEN JONES, for example, was a man so surfeited with the study of ornament that in his later years he made the attempt to dispense with it altogether; and BURGESS on a memorable occasion, when speaking more thoughtfully than at some other times he did, said plainly, "If I were obliged to choose between the mouldings and the colour, I should keep the colour and sacrifice the mouldings." But, all this admitted, we are still unable to allow that the false economy of the typical architect is accounted for. Not the architectural details alone, but the structural substantiality is too often compromised. Sometimes indeed, even while the æstheticals of a design are successfully smuggled through, it is the thin walls and the weak timbers that allow this to be done, and against a rich altar-piece there has often to be set off a perilous foundation. We refer, of course, to cases of what is called good work, not to buildings palpably scamped; and we need not hesitate to add that in many cases the whole extra cost of the little extra strength in cube walling and cube timber, which, without involving any more workmanship to speak of, would make the building "stronger than strong," would be so small a proportion of the total as to be inconsiderable.

As a principle a judicious Englishman will cheerfully pay for real solidity and durability in all things, and as cheerfully

dispense with ornament. He may be unable to afford the ornament, but he is never unable to afford the substance. Add to this the further consideration which cannot be too urgently repeated—that the difference in cost between a little below the mark which will soon give way and a little above the mark which will last for ages is generally much more trifling than we suppose. Lastly, is there not a beauty in mere strength itself that commends itself to every eye?

## AN ARCHÆOLOGICAL FEAT AT TURIN.

[BY A CORRESPONDENT.]

THE exhibition held this year at Turin is so important in the eyes of Italians that it might perhaps be wished that the neighbouring nations had taken a more sympathetic interest in the event than they have in fact displayed. The show is national, not international, and marks the first pause which the country has made for testing its progress in the arts and industries of modern life. It was for her own sake, and, as it were, before her own tribunal, that Italy made this trial; nevertheless, she wished to display to others what she was bent on proving to herself, but those others have been somewhat inattentive. Perhaps there is not full sympathy yet in the world for the progress of manufactures in a country the purity of whose sky and the picturesqueness of whose peasants are in a sense European possessions. The industries that are smearing coal-smoke over the blue and gold of Italian horizons, and drawing the shepherd and the ploughman off the soil into the crowded alleys of the towns, do not receive enthusiastic applause even from the foreigner who is well content that his own sky should be black and his own cities congested. But though the exhibition is mainly devoted to manufactures and modern industries, it has a very notable section devoted to history and art; and here a memorable work has been achieved in the construction of a castle and village which, unlike such revivals amongst us, are not only the semblance but the reproduction of the ancient forms. The undertaking combined in a remarkable degree historical research with invention; for the architect has not copied entire buildings of the period he had to illustrate—he has done his work according to the strictest authority, but as a sufficiently original architect of that time would have done it; and for this task was needed a considerable assimilative power. Signor D'ANDRADE, who has sacrificed rest and ease and has devoted all his powers to the effort of producing this huge work in the space of two years, is a Portuguese amateur, who has employed the fruits of his enthusiastic studies almost entirely in the service of Italy.

That nation, proverbial with the poets for misfortune, has nevertheless some signal good luck in her history. She has passed, since immemorial times, with no real pause, from one civilisation to another. In no European country has the tradition of art come down with so little intermission. From Etruscan to Roman, with the addition first of Greek and then of Byzantine influences; from Roman to Teutonic, with the modifications that seemed to spring from Lombard soil; from Teutonic to Moorish, art passed on in Italy to the Italian period, with revivals and corruptions, but with no cessation. Such a record could hardly be summarised in an exhibition of modern progress without occupying a space too great for the purpose of the show. Signor D'ANDRADE proposed, therefore, that as the exhibition was to take place upon Piedmontese ground, a specimen of Piedmontese historic art should be produced, and produced completely, in the characteristic form of architecture, and referring to an important period represented by very fragmentary remains—the close of the Middle Ages. Those remains were sufficient for the archæologist to work from, but they made his work necessary inasmuch as they were not sufficient to present any popularly intelligible idea. The year 1400 was chosen. Military and civil architecture were to be specially represented; ecclesiastical forms of the time, having received the attention of students elsewhere, were to be less prominent.

Signor D'ANDRADE has ransacked Piedmont for its antiquities. To know "everything of something" is one of the aims of sincere study, and he has been resolved to know everything of Piedmontese architecture. There is not a hill or a valley, a city or a village of the lovely sub-alpine province that he has not searched; and it is probable that not one old brick has escaped him. And from a field believed to be the

most unpromising in Italy he has gathered enough for the unique reconstruction which stands now upon the borders of the Po.

The village claims notice first, standing as it does at the feet of the castle, which can only be reached through the one gate in its walls, and by its one street. Its fifteen or so buildings form a most picturesque little group; its walls being some grey, some brick, some painted in vivid colours which show brightly against the darker castle walls. The north side, on which stands the gate, is protected by a palisade, moat, and wall. That corner of the wall which is towards the Po bears a round wooden-roofed tower, whence the first resistance would be made to an advancing enemy by the discharge of stones. In the centre of the wall is a square tower, also roofed, and having a turret at the side for the purposes of outlook. This tower has a door which is reached by a drawbridge thrown across the moat. Its face is painted with a decoration imitated from one in existence on the remains of a neighbouring castle. The design is in compartments enclosing a *Madonna receiving the Dove*, the *Angel of the Annunciation*, a *St. George*, a coat-of-arms, and, below these, a hairy demon brandishing a club. With these paintings are the legends—

In mundo spes nulla binis  
Spes nulla salutis  
Sola salus servire Deo  
Sunt cetera fraudes. Ergo nolo.

Si pacem portas licet has tibi tangere portas  
Si bellum geres tristis virtusque recedes.

The peaceful visitor thus welcomed gains immediate entrance to the village "piazzetta," whence the one street winds away on its narrow course. The smallness of the houses and the strength of the grey walls show how little the purposes of home, and how much the purposes of defence, were served by village dwellings of the time. If the women were ever content to abide within these dark doors, the men must certainly have lived outside; and in time of hostilities, when the drawbridge was raised and the one little portcullis lowered, even open-air quarters must have been narrow enough. The Piedmontese villagers seem indeed to have devised jokes, within their restricted space, for the stimulation of the necessary habit of laughter; for the first house is painted over with a curious and elaborate design—*The Dance of Fools*. The "fools" were societies of the sprightlier spirits who, according to a Piedmontese custom, undertook the amusement of town and village communities by organising festivals, ordering games, banquets, and plays of an elaborate character in the cities, and of every degree of simplicity in such a *borgo* as this at Turin. These societies played their part in the little events of private life. At weddings they were particularly active, taking toll of the bride before she was allowed to reach the church, and persecuting those who ventured upon a second marriage by a horrible *charivari*, only to be silenced by a banquet proportionate in liberality to the dowry of the bride. A henpecked husband was the chief victim of the fools, who seized the unhappy citizen, mounted him upon an ass, and led him by force in a grotesque procession. The fools, moreover, had the power of compelling the *facchini* to sweep the piazza before their games, and the stall-keepers to provide material for their feasts. In the painting six figures are shown—men and women alternately—the ladies standing most decorously, each holding a flower, like the queens of a pack of cards, while the men are contorted according to a very Italian idea of humour. Under the richly-decorated portico, formed by the projection of the upper storeys of this house, and supported by massive columns, stand open shops; close by is the public fountain. But the most important house in the village is that of the Pilgrims, standing with ever open doors for the reception of poor travellers to and from Rome and the Holy Land. Such journeys were difficult and dangerous at a time when provinces, cities, and families were divided by Guelph and Ghibelline, and when the lawless class of *fuorusciti* abounded in every district of Italy. For picturesqueness no building in the village surpasses the inn, with its courtyard, its tower, its open pilastered loggia, which collects deep transparent shadows under the projecting roof (then as now used for such domestic processes as require light and air), the groined vaults of the round-arched loggia of its first storey, and the high pointed arches of its portico below. The character of these loggias is altogether special, and has, as its authority, a house at Avigliana, the ancient village which stands guard over the Alpine valley of Susa.

In passing to a minute examination of constructions and of ornament, the visitor who has the benefit of the explanation of those responsible for the authenticity of details, will be convinced that all has been studied with the patience of antiquaries and the delight of artists. From the tiles of the roofs to the pavement of the porticoes and the shops all has been taken from existing models. For instance, in a house which is imitated from one standing at Bussoleno, also in the Val di Susa, the arrangement of the beams of the ceiling with deep recesses between, surrounded by various woods, is quite unique. The hinges and the lintel of the door, the projecting roofs, of the shops outside where the carpenter and the blacksmith are labouring at their trades, prove the minuteness of research. The bricks were made for the purpose according to the manner of making in 1400. And this faithfulness has produced an extraordinary variety in the forms of the arches, rounded or with extremely short lancets; in the windows, simple or divided into four compartments by stone crosses, furnished with glass or "*impannate*" with linen or paper, with iron bars projecting or mortised; ogees of brick or of terracotta, of natural colour or painted, with plain or twisted copings; capitals of brick or stone; sculptured or painted friezes; corbels of strange fashion and curious work; chimneys of all forms; divers coats of arms; iron rings. There is authority, as the architects declare, for every nail. The beautiful façade of the church, with its curious paintings of *St. Christopher*, the *Annunciation*, and a monastic saint holding a hairy devil by an immense chain, has been inspired by the churches of Verzuolo and of Ciriè, while the painted terracotta friezes and the crowning wooden parapet of the neighbouring house are from Cuorgnè. Among the houses which face the Po is one that has its façade crenellated and most elaborately decorated with coats of arms. It is from the river that one of the best views is to be had of the constructions. In many instances a wooden framework was made before the building of the walls, and one of these houses is raised on pillars in order to obtain a level for the ground floor.

Civic architecture in the village has not been studied more carefully than the military and feudal architecture of the castle, which overlooks the *borgo* and the river. This noble construction is intended to represent the dwelling and fortress of a feudatory of the first rank; in the former character it has all the luxury obtainable by a Piedmontese baron in the fifteenth century, and in the latter it stands as an example of a first-class stronghold. A huge mortar protects the northern angle: a round tower is on the south. The castle is surrounded by a moat, over which rise battlements and machicolations for the defence of the garrison by the casting down of stones and boiling liquids.

The only door is in a right angle formed by the junction of two wings, and is reached by the road which climbs from the village and crosses on a drawbridge. This door has pointed arches, and is an admirable work in stone, imitated from the castle of Verrès in the Val d'Aosta. It is closed by a portcullis of prodigious weight, within which a part of the garrison may be stationed, while others are posted at the double machicolations which overlook the drawbridge. If the enemy had succeeded in making an entry before the lowering of the portcullis, he would be narrowly enclosed in a vestibule leading to the door which gives access to the castle courtyard. From this point inwards, the study which has been made of domestic architecture becomes more interesting than that of the defences. The cortile is a reproduction from the castle of Fénis in the Val d'Aosta, and is a trapezium in form, the longest base facing the entrance. A steep semicircular staircase of yellow stone divides into two flights no less steep, which lead to a loggia, and are protected by massive stone parapets. Above the loggia of the first storey is another which runs round three sides of the courtyard, and is upheld by small columns of wood. From the ground floor steps descend to right and left to the underground constructions. The composition of lines is exceedingly felicitous. In decoration this cortile is fantastic. Up to the lower loggia the side walls are painted with a black-and-white rhomboid design, and over the semicircular open stair is a painting of *St. George slaying the Dragon*. Above, on the wall within the lower loggia, is a series of single figures of saints and friars, each bearing a legend in old French, pious or philosophical. High above a principal window are the carved arms of the House of Savoy, painted in brilliant colours; and between this and the door, the arms of the Counts of Challant, who were great lords in the Val d'Aosta and owners of most

of the castles in that region. On either side of these are smaller coats-of-arms, such as those of the Marquises of Monferrato and of Saluzzo, and of the Counts of San Martino and of Manta. The wooden carvings of the pillars of the loggie are of exquisite design and delicacy.

The courtyard communicates with the soldiers' rooms, with the kitchen, and with the baronial dining-hall, which has a ceiling (from a castle in the Canavese), all the wooden partitions of which are painted with elaborate designs, hardly to be discerned in the faint light given by the narrow and deeply splayed windows. No less thorough has been the care bestowed by Professor GILLI upon the furniture. Adjoining is the vast kitchen, with its vaulted ceiling, its spacious hooded fireplace, its well, ovens, dispensaries, and little doors for passing dishes into the hall. The rooms of the first storey open out of the loggia; chief among them are the chapel, which is over the dining-hall, the hall of audience, and the nuptial chamber. Over the vestibule runs a closed gallery, painted in fresco, and ending in the only large window of the castle, through which provisions are lifted in from the valley in time of war. For the chapel and its decorations authority is to be found in the castle of Manta, in the sacristy of a church at Ranverso, and in the choir of San Giovanni at Saluzzo. Its plate and other utensils are real remains of the period. The baronial bedroom is oblong, and hung throughout with old arras, its low wooden ceiling being in square compartments, richly decorated with roses of gilt bronze. The high bed is furnished with steps, which open for the storing of linen. The châtelaine has her little oratory on one side, and the chamber is furnished with praying-chairs.

Perhaps the most lifelike picture is that presented by the soldiers' room, or vast *corpo di guardia*, on the ground-floor, with its two huge, smoke-blackened fireplaces, its hacked and hewn tables, its stands of arms and armour, and its groups of braves casting dice, eating their rough food as they sit on piles of straw, or polishing the rust from their arms. These parts are played by stucco figures clad in costume. In the subterranean vaults are the cellars and the prisons, each fitted with their own suggestive appliances.

A little host of artists and architects have worked under the direction of Signori D'ANDRADE, BRAIDA, PASTORIS, and GILLI; as to the workmen, they were simply ordinary artisans, inspired by the instruction of their employers. "When an Italian workman has a good will," says one of the architects, "anything in the world can be got out of him." In this case his part in the great Turin achievement has been little short of marvellous. No need to say that the castle and village will be permanent; the municipality of the city has already bought them for perpetual preservation.

## REPORT ON WESTMINSTER HALL.

By J. L. PEARSON, R.A.

WESTMINSTER HALL was erected by William Rufus, in 1097, as the nucleus of an extensive palace he proposed building on the site of that probably founded by the Confessor, and enlarged by the Conqueror. Additions, alterations, and surroundings, from time to time, had served by the beginning of this century almost completely to conceal the original work of Rufus. There remained only in 1834 a couple of windows and parts of a string course on the east side to tell of its existence. During the restoration of the north front, when Lewis Cottingham's drawings were made, considerable portions were for a short time uncovered, and again in 1834-35, the whole of the Norman walls were laid bare to be re-cased by Sir Robert Smirke. It has remained for the late removal of the Law Courts on the west side to uncover permanently a large portion of the earliest Norman walls, fortunately in a fairly perfect state of preservation.

The following is a brief list of the various dates when extensive alterations, either in the nature of additions, repairs, or damage took place at the palace, more especially at the hall. These are numbered for further reference, and the information has been verified by original documents as far as possible.

1. William II. (1097).—Foundation, by William Rufus, of the great hall.
2. Henry II. (1163).—Probable repairs and alterations, possibly by Thomas à Becket.
3. Richard I. (1199).—Repairs by Richard I. No traces remain.
4. Henry III. (1217, 1221, 1224).—Throughout Henry III.'s reign extensive works were proceeding at the palace. At the same time the choir, transepts, and Lady Chapel of the Abbey

were being built. Extensive decoration was also in progress. (1244, 1263).—Probable date of the Early English work at the north-west angle of the hall, of which traces are now visible. Fire at the palace.

5. Edward III. (1297 or 99).—Great fire, which reached as far as the Abbey. This indicates that the fire was on the west side of the palace, and, as a consequence, Parliament had to be held at the house of the Archbishop of York, at Westminster. Edward III. built, adjoining the hall, a room for "the hall of the family in Parliament time," from which we gather that the great hall was used in his reign for the sittings of Parliament, and the fact that Parliament had to adjourn after the fire implies that the great hall suffered. In Edward III.'s reign, at the time of the building of St. Stephen's Chapel, reference is made to new work in connection with the hall.

6. Richard II. (1394-97).—It seems from Thomas Walsingham that it was customary for Parliament to sit in the hall in Richard II.'s reign. Whether to repair the damage which may have been caused by the last fire, or to make the hall more suitable as a Parliament House, Richard entirely transformed it to its present shape. The walls were raised 2 feet, and re-cased, and new windows were inserted. The existing roof was added; a new northern porch and towers, and the large buttresses lately uncovered were built. Also "divers lodgings" on the west side; these were mostly contained by a wall erected parallel to the hall, and connecting together the new great buttresses. The two tiers of wall arches between the Norman buttresses were also erected at this period.

7. Richard III. (1484).—Repairs by Richard III. No traces visible.

8. Henry VIII. (1512).—Great fire, which destroyed a large portion of the palace; never rebuilt, and in consequence of which Henry VIII. removed to Whitehall in 1529.

9. Elizabeth (1570).—Large additions to the west side of the hall. A large part of the work built at this date remained until 1822.

10. Charles II. (1680).—Additions by Sir C. Wren.

11. George II. (1732).—Courts of Common Pleas and doorway on west side of hall; also committee-rooms along St. Margaret's Lane; all by William Kent.

12. George III. (1793).—Widening of St. Margaret's Lane, whereby part of Elizabeth's work was demolished.

13. George IV. (1820).—Sir John Soane began work of demolition previous to the erection of his Law Courts.

14. George IV. (1822).—Restoration of north end by Thomas Gayfer, mason to the Abbey of Westminster.

15. William IV. (1834-35).—Re-casing of the walls of great hall by Sir Robert Smirke.

For those whom it may interest, after a description of my plans for the proposed restorations and additions, I will revert to the above works, giving a more detailed account of them and of the traces which now exist.

In making my plans for the reconstruction of the west side of the hall, it has been my object consistently with present requirements to recover the aspect which it presented in Richard II.'s time; also to retain the existing evidences of earlier and later historical work. I, therefore, propose to rebuild the wall between the buttresses in its original position, making an open cloister with a gallery over it extending nearly the whole length of the hall. This cloister will be formed by a series of arches which are not only suggested by the wall arches inside, but by the existing jambs I have found against the large buttresses, and also from the evidences supplied by Capon, from which it is not improbable that this was the original treatment.

The height of this cloister wall is accurately marked by the returns of the parapet on the buttresses, and I have no doubt from the position of these that the parapet was embattled (my reason for this will appear later). Quite apart from the fact that I consider the introduction of this series of arches (forming a cloister), and also the gallery over them, as of great importance to the dignity and effect of the whole building, and that it is, therefore, from a purely architectural point of view, the treatment I would desire to see carried out, I have been to a large extent induced to propose it, and to urge its importance by my desire to further as much as possible the preservation of the most interesting and ancient part of the work which remains to us, namely, the Norman wall of Rufus, lately uncovered, which is the more valuable because it is the only remnant of that early period which now remains exposed throughout the building. Its destruction I should regard as a great loss, but this is assured in a few years, if the wall is to remain unprotected, because its materials are notably unable to resist the attacks of the present London atmosphere. It has suffered already from its present short exposure. I regard the erection of this cloister wall, therefore, as a method of at once preserving this Norman wall and of leaving it exposed to view; one that can satisfy antiquarian sentiment as well as reason. The reconstruction of some of the great buttresses of Richard II. is justified on the strongest grounds, those of stability; they are at present in a most dangerous state, so much so that I cannot remove some of the brickwork which Soane built against and around them, lest they should entirely collapse. It must be borne

in mind that their present state is but little due to the lapse of time, for the most part to injury and defacement of quite modern date.

I would here say that I fully appreciate the value, historical and otherwise, of the effects which time produces on stone, and I would always endeavour to preserve them when possible. But when stonework has been mutilated so as to completely destroy all its features of interest and value as well as these effects of time, it seems more than unreasonable to preserve what are merely evidences of a want of consideration and respect for ancient work.

It would not, I venture to think, be much less than absurd in the present case to retain in their place the bricks, tiles, and plaster with which Soane and Kent, merely to serve the purposes of the modern work they erected, surrounded the buttresses.

(To be continued.)

## BEVERLEY MINSTER.\*

I DO not propose this morning to enter into details of the ancient history of the beautiful building we are now visiting, our time being limited. I shall only mention one or two points that I think may add to the interest of the inspection we are about to make. The church was dedicated to St. John the Evangelist, or St. John the Baptist, and was founded as a monastery early in the eighth century, by John Harpham, fifth Archbishop of York, who is known as St. John of Beverley; he was a saint held in very high estimation; his banner was, on several occasions, carried into Scotland by the kings of England when invading that country, and amongst others was King Athelstan, A.D. 919. They, on their return, as thanksgiving for their success, gave many rich gifts at the shrine of St. John; the latter gave a large sum of money to the church, as well as the gift of Sanctuary, which was enjoyed until the Reformation. A painted tablet, in the south transept, with the figures of St. John and King Athelstan, records this event; a stone chair still remains (which I will point out to you when we go round the church); it is supposed to have been the Fridstool, brought by King Athelstan from Scotland, and any criminal who reached this seat claimed the right of Sanctuary; his life was spared, no matter what had been the nature of his crime; but the remainder of his life was devoted to penance and servitude to the Church. I am told that the only other example in England is at Hexham, but you will remember that yesterday we were shown a seat at Halsham which it was stated was a Sanctuary Chair; and he found that a chapel in this church was dedicated to St. John of Beverley, so that there may be something in the claim.

Considerable importance was attached at all times to the office of Provost of the Minster, and many eminent men have held that office, amongst others St. Thomas à Becket. The church built by St. John and King Athelstan was consumed by fire in 1188, in the last year of the reign of King Henry II., on the night following the Feast of St. Matthew the Apostle (21st Sept.), and upon the site of the ruins of that building the present edifice rose. In reference to the rebuilding of the church I will mention one point which is of importance in helping us to account for some of its peculiar features, viz., that in the year 1311 a writ was issued for the purpose of arresting certain persons who were travelling about the country collecting funds for the building of the Minster, and falsely representing themselves to be messengers from the Chapter of Beverley. This fraud was very successful, and no doubt caused the work to be stopped; also it may account for the omission of a link in the architectural progression of the work, between the severe Early English, as seen in the lancet windows of the choir and transepts, and the rich windows of the north and south aisles, of the nave, of the Decorated period, instead of windows in the Early Decorated or Geometrical style, such as are found in great perfection at Bridlington Priory Church and in Hull. The plan of the fabric consists of a nave with north and south aisles and transepts at the crossing, with east and west aisles; the choir has north and south aisles, transepts, and a small chapel on the north side, built about the year 1490.

The extreme length of the Minster is 332 feet, and the breadth across the transepts and crossings is 167 feet, the height of the vaulting is 65 feet. It would almost seem by looking at the size of the piers at the crossing, that a central tower was intended to have been erected; I do not incline to the opinion that this was the original idea of the builders, but to the theory that the tower or flèche was designed (and in fact partly executed) to rise from the intersection of the eastern transepts, for the following reasons:—You will notice that the piers of these transepts differ considerably from any parts of the remainder of the church, and appear less striking in design, especially the upper portion immediately below the clustered circular shafts. Now if you examine the piers of the larger transepts, you will find that they exactly correspond with the upper portion of the smaller transepts, and I think that these

\* A paper by Mr. F. S. Brodrick, architect, read at the visit of the Lincoln Diocesan and Yorkshire Architectural Societies.

circular shafts originally came down to the floor level, with the idea of their carrying the proposed tower; then, when it was abandoned, they were found to look heavy, and obstructed the view of the east end; the architect, therefore, conceived the plan of cutting them down to open out the arches. I am further confirmed in this opinion, by the fact that above the groining at this intersection on the east side of the west arch, are to be found remains of arcading, similar to that in the transepts, and it is continued round all the sides of the square, as if intended to be visible from the church. Mr. Willis, after an examination with Mr. Petit, has written in some notes of the proceedings of the Archæological Society that he considers the church was originally intended to stop at the intersection of these transepts, and that the arcading was part of the east gable of the church, and was, of course, outside work. I produce an enlargement of his sketch, with an addition of my own in red ink (which was probably not uncovered when Mr. Willis saw it), made after an examination of the work. This addition, and the further fact that the shafts are of Purbeck marble, which would certainly not have been used on the exterior of the building, throws doubt on his view of the matter. The Holy Well is just beneath this intersection, and may have had something to do with the selection of this position for the tower. I throw out these remarks as a suggestion only, and should be glad to hear other opinions on the question. The present tower, or whatever name may be used for it, was erected, together with the vaulting (which you will see differs from the remainder of the church) in the last century; it had a cupola upon it originally, but this was removed in 1824. The earliest portions of the Minster are the transepts and the choir with their aisles; they are of Early English character, date about 1250; the cruciform plan of the choir itself is a feature. The piers of the choir present a very beautiful appearance, suitable to the weight they have to sustain. You will notice the varied effect produced by the introduction of the vertical fillet in some cases, and in others by the shafts being brought to a point.

I would call your special attention to the beautiful triforium, or blind storey, between the arcades and the clerestory. Each bay has four trefoil arches enriched with the tooth ornament resting upon clustered shafts, and touching the wall is a second arcade with pointed arches, the intervening space being filled with a sunk quatrefoil. The architect of the nave admired the triforium to such an extent that, although the work had passed into the Decorated period, he reproduced it without alteration, excepting the omission of Purbeck marble shafts; thus you have the peculiar effect produced, of Early English work surmounting work of the Decorated period, and this has, I believe, caused many learned discussions at different times as to the actual date of this part of the fabric. This triforium differs from the usual form in not having a passage behind it; it is, in fact, simply bare panelling. The easternmost piers of the nave with the arches are Early English, but all those to the westward are Decorated in character; the plan of the piers is the same (again showing the appreciation by the architect of the old work), but the caps and bases vary and foliage is introduced, larger hollows occur in the arches, giving greater light and shade. The clerestory also differs in design, and the ball-flower of the Decorated period replaces the tooth ornament of the Early English style; also the windows have decorated tracery, and are of two lights. The Decorated work extends on the north side as far as the porch, and on the south side as far as the arches of the tower. The tracery in the windows is of flowing character, and particularly rich in design and variety. The lead-work is also worthy of notice. The arcading below the windows is most interesting, as showing examples of the three Periods in which the Minster is built—the Early English at the eastern end, the Decorated following, and finally the Perpendicular of the west end. I think you will agree that the eastern or Early English portion is the most graceful and pleasing in its effect. The Perpendicular work is a bad copy of that of the Decorated period, and the shafts are not of Purbeck marble, but are painted.

The sedilia are worthy of notice, being the only remaining part of the old stalls, and are of the Decorated period. The stalls themselves present an almost unrivalled series of carved misereres; the date is about 1520, it is carved on one of the misereres about the centre, and they would repay a careful examination. I also think that the careful way in which the modern work is combined with old is worthy of much commendation. To give some idea of the enormous foundations required for a church of this description, I may mention that the footings of the nave piers are so large that they almost touch in the centre of the building, and do not leave more than 3 or 4 feet between them. The western towers seem hardly to have been part of the original plan; at all events the Decorated work is continued right up to the present front on the south side, and, in fact, some 3 feet beyond, fragments of which I will point out to you as we go round. The windows of the aisle to the west of the north porch, and the corresponding windows of the north tower, are of Perpendicular work, but strongly tinged with Decorated feeling, as shown by the shafted mullions with their carved caps and moulded bases, and the jambs. The towers will be best understood by an actual inspection, but I may mention that the height to the top of the pinnacles is 180 feet.

## THE SANITARY ARRANGEMENT OF HOUSES IN LONDON DURING THE LAST 120 YEARS.\*

BY FRED. W. HUNT.

THIS subject is one that may be dwelt upon in detail, or by sections, to an extent sufficient to occupy the undivided attention of to-day's meeting, or of several meetings. In the short time, therefore, allotted to its consideration in the proceedings of to-day, I cannot do more than refer in general terms to some of the chief points that have occurred to me.

In speaking of the sanitary arrangements of houses in London during the past 120 years, the points that present themselves for especial consideration are—

1. Drainage and the appliances in connection with it.
2. Water service and its supply and arrangements.

But besides these two subjects, if time allowed, there are further to be considered—

The general arrangement of the houses during that period, and the use of the several parts, and their ventilation. All these being subjects that may be dwelt upon, not only generally but in detail, and also according to the several classes of houses that are to be met with, and are still required, for the wealthy and well-to-do, as for the poorest of the community.

*As to the question of Drainage.*—I must first make some allusion to the general drainage of the Metropolis; for the drainage of houses is dependent upon that of the town in which it is situated.

Before the commencement of this century there was not any system of public or general drainage existing. It is true there were both open and closed "sewers" so-called, but these had been provided for the purpose of carrying off surface water only, or for conducting fouled streams along their old courses. As new squares and streets were laid out and houses erected, sewers were formed under the new roadways, but these were still only for surface water, and it was illegal to conduct any fæcal matter into them. In the formation of these sewers, as they were only for surface water, the questions of a proper fall, or construction with a view to proper cleansing, do not seem to have been considered essential by the engineer or builder. When, after 1815, it was allowed to carry the overflows from cesspools and other foul drains of houses into sewers, the existing sewers, constructed for the purposes before mentioned, were used, and some have continued in use until the present time, being *sometimes* only elongated cesspools with the outfall higher than the upper end.

I should state that the sewers and drainage of the Metropolis had been under the care of the Commissioners of Sewers for the several districts for centuries, and they so continued until the Act 1855, under which the Metropolitan Board of Works was formed. Since that time the general or main sewers have been vested in that Board, while others remain under the care of the several Parish or District Boards.

To come now to our question, which is house drainage. It was necessary, as will be readily seen, under the circumstances above alluded to, viz., that when there were not any sewers for the reception of house drainage, each householder, large or small, had to provide for the reception and storage of all soil or refuse upon his own premises, until it could be removed with as little annoyance to himself or his neighbour as possible. The arrangements of houses therefore in the Metropolis differed but little from those of the country, with the exception that those in town had not the space or accommodation the country afforded for the conveniences required.

Much refuse that is now discharged into the drains was no doubt at first thrown into the streets, but as the regulations forbidding this were enforced, cesspools or cesspits were the means provided for the reception of all soil and sewage matter. These were usually constructed in the yards or gardens of the larger houses, which were provided with one or more privies, frequently arranged so that a common cesspit would answer for them; while for poorer neighbourhoods and courts, one such convenience was provided, to be used in common by the residents of several houses.

House drains, similarly to sewers, were originally constructed to take the waste and surface water, and being for this purpose only, they were not very carefully laid, and were generally square in section, and frequently without any paved bottom. These drains were connected with the sewer if one existed within reach, otherwise they had to go to a cesspool. In houses built after, or only immediately preceding the commencement of this century, when the introduction of a watercloset into houses was becoming general, the drains were made of brick, circular in form, and such as are now called brick barrel drains. These drains were constructed with mortar as a rule, though sometimes a portion of the bottom was laid in cement, and they still discharged into cesspools from which overflows were carried away. No doubt the overflow was frequently connected with the public sewer, but it was not until 1815 that the penalty against such connection was removed.

\* A paper read at the Conference of Architects at the International Health Exhibition.

With this means of overflow, and drainage allowing as it did of the use of a greater quantity of water, and at the same time obviating the necessity for emptying cesspools so frequently, water-closets instead of privies were generally provided for houses built at and after the commencement of this century, not only internally but externally. The difficulty that then presented itself to the builders was the keeping back of foul smells, which was provided against by traps in soil pipes and dip traps at the bottom of pipes, frequently so large that they might be called cesspools.

Previous, therefore, to this century, and for the first quarter of this century, we find a gradual suppression of privies, and the introduction into houses of water-closets, using the old flat bottom drains, or such drains as had been originally laid down, and these discharging into cesspools. It appears to have been considered that a drain would do for any purpose the needs of the occupier might require it to serve, and now all faecal and offensive matter could be washed away out of sight, and traps were supplied to keep back offensive smells, it was sufficient to allow this refuse to find a lodgment in cesspools under the floors of the house, or for that matter on the surface of the ground under the floors. When one cesspool became no longer serviceable, rather than cleanse it a new one was made, and the drain directed to it. The site selected for the new cesspool was one that was convenient for the drain rather than for the health of the house.

I have referred to this as the state of things existing for the first quarter or so of this century; I ought rather to say it is the state of things that came into existence then, and continued for many years afterwards. Subsequently, when sewers were allowed to receive all drainage and refuse from houses, cesspools were no longer constructed, but the old ones were only gradually disused, and a similar influence as before was still at work, for the old drains were retained and diverted only—the cesspools were not removed, they were only disused and left; in fact as little alteration or improvement was made as possible, and frequently that only by the order of the authorities.

It was not until 1847 that compulsory powers were first granted to the Westminster Commissioners of Sewers, enabling them to require all houses to be properly drained into the public sewers, and privies and cesspools no longer constructed or used. These powers were subsequently granted to all Commissioners, but the enforcement of these powers was very gradual, and incomplete houses built before or in the very beginning of this century are still to be met with which present examples more or less of combinations of all the systems named. Old flat bottomed or no bottomed drains still in use, or very imperfect pipe-drains laid in the course of the old drains, with large dip-traps, and water-closets without water laid to them, and cesspools, not used perhaps, but that have never been cleansed or emptied.

About 1850, earthenware pipes came into use for drains, and these, with various improvements in their glazing and manufacture, are to the present time the most approved material used for house drains.

After the introduction of pipes for drainage purposes, the principles observed in the laying and construction of drains continued, however, much the same. The fall of the drains was not improved, and they were laid with very imperfect joints, sometimes not jointed at all. Dip-traps equal to cesspits were still built. Drains were brought into houses and rooms, and connections made there, and the offensiveness arising from the sewers was still overcome by traps and water-seals.

Much has been done during the last few years in advancing sanitary knowledge, and I think I may summarise the principles gradually accepted, and now more generally acted upon as being increased fall to drains, perfect water-tight joints, the abolition of dip-traps, keeping all drains outside the house, disconnecting them from the main sewers, the efficient cleansing of drains and the quick removal from them of all obnoxious matter, the separation of surface and sink and other wastes from soil drains, and a continual free current of air through the drains from near their entrance to the sewers along them and up the soil-pipes.

*As to the Appliances.*—One hundred and twenty years since, water-closets, as such, had scarcely been introduced, though water had been used as an agent for removal of soil; for some accommodation other than commodes, and more private and convenient than outside privies, were demanded by those who could afford to pay for them and their fitting up.

The form of such closet at first in use was no more than a receptacle capable of being washed out, from which a pipe was carried to the drain, having a plug to close the upper end, somewhat like a hopper-pan without a trap. This was fitted up in a cupboard or in a room, where convenient to the occupier, and provided with a seat and lid.

The great difficulties of attending to privies and cesspits to houses built in streets and terraces, and the annoyance from them, led to the great development and the introduction of water-closets and the improvement of the apparatus by various inventors, whose object appears to have been to provide for a regular supply of water for cleansing the pan or receptacle, and the keeping back of foul smells. Many so-called water-closets were, however, only pans, with a trap under, to which water was not laid on, but had

to be supplied by hand; and some of these continue in use to the present day.

Between 1770 and 1780 the first on record of several patents were taken out for an improved apparatus. The earliest were on the principle of a valve closet, but the kind of apparatus known as the pan closet, with a large container, came into use very generally at the commencement of this century. The apparatus of each kind has been improved by various inventors from time to time, and their introduction facilitated, by cheapening the cost of them, as well as by the demand of the occupants. I do not propose to express any opinions as to the best kind of apparatus, but I may say that those which provide for being the most efficiently cleansed by the service of water are now most recommended.

The pipes from the apparatus to the drains have usually been made of lead. Other materials, such as earthenware pipes and iron pipes, have been used, but each of these were found to have faults greater than lead pipes. When it was found necessary to keep back foul smells, D-traps, and traps of various kinds were introduced. These were formed in connection with the pipes, and a dip-trap was built at the bottom of the descending pipe. As offensive smells were more objected to, the traps were increased in number and size, but the gradual acceptance of the principles now acted upon, and referred to above, has gradually led to the abandonment of the dip-traps at the bottom of the pipe altogether, and to constructing one trap near the apparatus, as small as possible, and with earthenware rather than lead or a material subject to corrosion.

*Wastes from Roofs, Sinks, &c.*—At the first, the removal of water from roofs, and of surface-water, appears to have been quite natural. It was conducted into the water-channels in the streets, or by drains, into the sewer under the street, and it was only after the discharge of the foul sewage into the drains that any special care and precautions were felt necessary. The method adopted was again the same as above alluded to, viz., dip-traps were built and water-seals depended upon, and then the same descending pipe, as well as the same drains, were used for wastes of all kinds. This continued to be the principle of the system followed until very recently, and is still followed more frequently than may be generally supposed, instead of the separation of the waste from the soil-drains now recommended.

*Baths.*—These are fittings that were a luxury scarcely known before this century. They were very little used even some thirty years ago, but they are to be met with now in new houses of 30% per annum or under. Lavatories are also quite a recent addition to the accommodation of private houses, and sinks for various purposes have been added almost without limit.

*Water Supply.*—The City, which doubtless had suffered for generations from the pollution of all springs and wells by percolation from cesspits, had been supplied more or less with water from outside sources since the fifteenth century; but the new districts around, that had grown up and were rapidly increasing, were not so supplied before this century.

The Lambeth Water Company was incorporated by Act of Parliament in 1785; the Vauxhall Water Company in 1805; the West Middlesex Water Company in 1806; the Kent Water Company in 1809; the Grand Junction Water Company in 1811.

Before the introduction and supply of water by the several companies, the residents were dependent upon the wells in their houses, or upon the parish wells or conduits. The more plentiful supply of water provided by the companies, and the disuse of wells, facilitated the introduction as well as the extended use of the apparatus for the water-closets, and later on of baths and lavatories.

The water supply to house was generally to one or more cisterns in the basement, according to the size of the house, one being placed in the front area; and when there was a second, it was placed at the back part of the house. At first as the facility for a high service was very restricted, and the cost great, it was seldom used. A small cistern was afterwards placed over the water-closet as such an addition was made to the houses, and the water companies were able to give a higher service.

The service in the house at first was by a tap in the side of the cistern, but it was soon extended to the sinks for convenience. The wastes from the cistern was generally by a trumpet-mouthed waste led direct to the drain, or to the trap under the water-closet apparatus, as the case might be, without any further trap or disconnection, and the supply was taken from the same cistern for all purposes.

For houses of a poorer class the supply was to one cistern only, or to one for several houses in a court, frequently situated near, if not over, the water-closet in the yard that it had to serve, and one tap was attached to this cistern as a draw-off for all other purposes.

The stable-buildings were at first supplied by means of a tank under the floor of the coach-house, which served not only stable purposes, but the family resident in the stable; subsequently a small cistern was added, at a higher level, to supply the water-closet apparatus and the residents.

*As to the Arrangement in Houses.*—When water-closet appliances first were introduced they were required as much, if not more, for houses already built as for new houses. Such an addition to

a house would appear to have been regarded as not more offensive or dangerous to the health of the occupants than the use of a commode, for which they were introduced as a substitute; and accordingly we find the water-closet was erected in a bedroom or in a position nearest and most convenient of access from the family rooms. The necessity for external ventilation or even light was not felt, or it would surely have been supplied.

The general position for the water-closet in the earliest days of its introduction was designedly in the centre of the house, near the best bedrooms, and where the descending pipes conveying the rain water from the roof was available for use as a soil pipe. Light and ventilation there was none, except by a fanlight or small window on to the staircase. Water-closets continued to be placed in this position until near 1850, and in large houses there were two or more so placed on the different floors of the house, and some that could have been as readily lighted and ventilated from the outside were not. The position of the water-closet for the use of the servants, and those in houses of the middle and lower classes, was frequently in the front vault, equally without light.

Houses formerly occupied by single families of the middle classes, but since gradually becoming occupied by a family in each room, have remained without any improvement in this respect. They are still only provided with one water-closet, with a hopper basin and a defective supply of water, placed in a vault in perfect darkness, and where cleanliness is really a difficulty to attain.

This necessary accommodation in houses of more recent erection, is always placed next an outer wall, with better means both of lighting and ventilating, though still in many cases it would seem as if there was a fear of admitting too much light or air.

Baths and additional cisterns and water services and sinks have been gradually added to houses, until at last they are almost without limit. At first baths were placed in bedrooms, but they are now more usually placed in a separate room. Sinks and safes under baths, &c., had their wastes taken to drains or soil pipes, but now they are made to discharge separately.

*Ventilation.*—I would make a few remarks upon this subject. In houses built about 120 years since and later, the reception-rooms in large houses, and even generally, do not call for any special remark in this respect, but the offices and bedrooms were arranged rather to give the greatest accommodation than the best.

Borrowed light and borrowed ventilation was not considered to be undesirable, and the height and dimensions of the sleeping-rooms generally were of the smallest dimensions. With a height of 14 feet for reception-rooms, a height of 9 feet often sufficed for best bedrooms, and of 7 feet for the upper bedrooms, while the upper sashes were frequently fixed. The changes adopted have gradually been to make all sleeping rooms higher, and give them all direct external light and ventilation, and to add other means of ventilation besides open windows.

As a concluding remark, I would say that the alterations in the sanitary arrangement of houses, during the period I have referred to, have been gradual, and until recently very reluctantly, adopted. It has been, and still is, a difficult matter to persuade people of the necessity of making such alterations to their houses; and some prefer to ignore the fact that their houses are in an unsatisfactory state. There is a very prevalent idea that officers of health and inspectors of nuisances have had all objectionable arrangements done away with, and that no one would think of allowing any such to exist; whereas, I think it is rather a fact that those officers never interfere anywhere until the arrangements have become most defective, and are a serious nuisance felt by all in the neighbourhood, and that they seldom think of inspecting or interfering with the arrangement of houses of the middle and upper classes.

### THAMES COMMUNICATION.

THE Select Committee of the House of Commons have issued the following special report on the proposed Thames subway at Nightingale Lane, and the duplex bridge to the east of the Tower:—

Your Committee were unanimous in their opinion that they could not recommend that the Duplex Bridge Bill should be passed, neither did they feel warranted in recommending the expenditure of 2,000,000*l.* of public money at the Nightingale Lane site, which could at best be regarded as a compromise, and which would have entailed an expenditure of a like amount further to the east.

Your Committee are of opinion that two crossings are immediately required, and should be sanctioned by Parliament. The one a low-level bridge at Little Tower Hill, with two openings, each about 100 feet wide, to be spanned by a pivot-spring bridge. The other a subway at or near Shadwell, which would be central, and would best meet the wants and wishes of the inhabitants east of London Bridge.

So far as a low-level swing-bridge at Little Tower Hill is concerned, much incidental evidence was given which enables your Committee to speak with some authority in its favour.

The approach to that site from the north could be made of sufficient width by a very slight concession on the part of the

War Office, and thus the heavy expense of purchasing any portion of the costly warehouses of the St. Katharine's Dock Company could be avoided without unduly trenching on the precincts of the Tower, while upon the south side there appears to be no property of very great value in the line of the proposed bridge.

The question of a swing bridge on the pivot principle, spanning two openings each of about 100 feet width, appears to have been most satisfactorily solved at Newcastle, where such a bridge has been constructed over the River Tyne, and has been proved capable of accommodating satisfactorily both the ship and road traffic. Two vessels arriving from opposite directions can pass such a bridge at one and the same time.

Evidence was given that the time occupied in opening and shutting such a bridge does not exceed three minutes.

Your Committee are also of opinion that this arterial communication should be constructed by one of the two great public bodies of London, either the Corporation or the Metropolitan Board of Works, and not by a private company.

It appears from a letter of the Chamberlain to the Remembrancer of the City, dated June 28, 1884, that the condition of the Bridge House Estate Fund is now such as to warrant a sum of 750,000*l.* being raised, and that a sinking fund could be created which would pay off this and the existing debt in thirty-five years.

This sum would probably suffice for the construction of such a bridge as your Committee have suggested, with adequate approaches; and your Committee cannot avoid expressing a hope that the Corporation of the City of London may be induced to undertake this great and useful work contemporaneously with the construction of a subway at Shadwell by the Metropolitan Board of Works.

### ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS.

THE annual meeting of the Association of Municipal and Sanitary Engineers and Surveyors was held last week at Newcastle-on-Tyne. An address was delivered by the president for the year, Mr. W. T. Laws, the engineer of the city. In the course of it he said that healthy dwellings for ourselves, in which hygienic laws shall not be set at defiance, is a subject upon which science, experience, and skill are ever at work, and in which individual needs will always be supplied by individual effort. Healthy dwellings for our artisans and labouring classes is a much more pressing question, which is taxing and will tax the utmost effort both of local and Imperial legislation. It is a question which civilisation has begotten, and which civilisation itself has rendered more and more difficult. Civilisation has crowded man into limited spaces by enabling him to have his food supplies brought to him on the spot where he finds the readiest market for his labour. But for the modern facilities for transport given by improved roads, by steamships, and railways, such towns as London, Glasgow, Liverpool, and many others could not exist for a month. No one who witnessed the effect of the great snowstorm of 1880-81 in London could help speculating on the critical nature of its position had the block to transport continued even for a fortnight instead of a few days. A population of four millions means a daily consumption of 5,000 tons of foodstuffs and the daily removal of 70,000 tons of liquid and solid refuse through the sewers. A month's stoppage of the supplies would mean starvation to thousands; a week's stoppage of the sewers would mean disease and death to thousands also. So that civilisation, while it has enabled men to live together in much greater numbers, has also rendered their position infinitely more critical, and necessitated special provisions for their comfort and safety as a community. And it has also led to the great problem of how to house the labouring classes. Space in the centre of London has become so valuable for manufacturing and business purposes that it is too dear to live upon, and the living links in the great machine, the flesh and blood without which manufactures and business must cease altogether, are driven to herd together in slums that are unfit for human beings to exist in; or they must migrate beyond that wide belt of middle-class dwellings which forms Greater London, and add to their daily toil a weary journey morning and night. This is a problem the solution of which calls for wisdom in deliberation and skill in administration. In all these problems, gentlemen, we municipal and sanitary engineers are called upon by our position as advisers and executive officers to take no small part. Every one of us has some share in one or more of them, and is, or may be, called on to-morrow, if not to-day, to task his brains to advise upon, and his energies to carry out, some part of them. And this it is that make the value of such an association as ours, and of such meetings as this where we can discuss the sanitary problems of the day, and compare and exchange our experiences. Sanitary progress is aided by our discussions, methods that have been successful are explained and made generally known, and, what is equally important, failures are published, their causes investigated, and similar mistakes guarded against in other places.

## NOTES AND COMMENTS.

QUESTIONS have been asked in the House of Commons respecting the delay in commencing the works of the Science and Art Museum in Dublin. It was implied by one of the Irish members that there was only a trifling difference between the estimates of Messrs. DEANE & SON and of the Government surveyor. In reply, Mr. COURTNEY was compelled to confess that the difference was not slight, and it was added that it would be entirely unjust to the other architects to proceed with the design recommended by the Committee without inquiring into the probable cost of their designs also. The amount of the difference between the two estimates has not been announced; but it must be the reverse of trifling, otherwise the Government, out of sheer weariness of the trouble connected with this scheme, were likely to have given orders to start the works. If it is established that the recommended design is much more expensive than the authors stated, it is the bounden duty of the Government to reconsider the report. We do not suppose for a moment that Messrs. DEANE knowingly produced a design that was incompatible with the conditions, but everyone who has had to do with modern competitions is aware that there are architects who consider it to be a diplomatic feat to send in designs which disregard the stipulated cost, believing that diplomacy will still befriend them when the builders' estimates appear. This is a practice which should be treated without mercy, and there are assessors who wisely make cost the first condition in examining designs, and set aside every drawing, however beautiful, which appears to exceed the limit. If the Government will insist on right being done in Dublin, their action will have a beneficial influence hereafter on public and private competitions. The erection of the building may in consequence be delayed for a month or two; but it should be remembered that if it were not for the clamour which was raised in Ireland when an English design was preferred, the walls of the museum might by this time have attained a good height.

WE have not space this week to print more than a part of the careful report by Mr. PEARSON, R.A., on the proposed alterations at Westminster. The works which are contemplated will cost 35,300*l.*, and come under three heads. First, an open cloister extending nearly the whole length of the Hall, and comprising the restoration of the buttresses and the west side of the Hall. The latter work will involve the removal of the already worn and dilapidated casing of the upper part, which was added by Sir ROBERT SMIRKE in 1834-35, and the substitution of masonry well bonded into the Norman core. The second will be the completion of Sir CHARLES BARRY'S work on the north side of St. Stephen's Porch, "in such a manner as he himself would have desired to have seen it completed under present circumstances." The third work will be the alteration and raising of the two towers at the north end of the Hall, which, although demanded by the extreme ungainliness of the existing front, must be conjectural, as there is no record to guide the architect as to their original condition. Mr. PEARSON proposes to alter the windows and raise the towers one stage. The difficulty of the task is apparent. Mr. PEARSON is the most conservative of restorers, and we fear he runs the risk, by his extreme care and reverence, of giving dissatisfaction to all but the judicious.

THE report of the Old Mortality Society states that in the following instances the advice of the Council has been obtained:—The preservation and restoration of Lord DACRE'S tomb in Saxton churchyard accomplished; tracing the representatives of MORANT, the Essex historian, and renovation, it is believed, of his tomb at Aldham; the replacement of Dean CANNON'S mural monument in Westminster Abbey; the preservation of the great Countess of CUMBERLAND'S tomb in the church of St. Lawrence at Appleby. Steps are in progress for the recovery and preservation of the ALINGTON monument (1626) at Mildenhall; the preservation from absolute decay of the DEANE monuments (1634)—fine works of art—at Great Maplestead. The Council desire to take action for the safety of the DE LA BECHE effigies (fourteenth century) at Aldworth; the preservation of the BARNEWELL tomb (1589) in Lusk churchyard, Ireland, and to aid in the recovery of the CULPEPER monument (1604) at Feckenham. The illegal removal of memorial slabs from churches is a great evil; an important case at Milford, Hants, will probably be tested. In

Paddington Churchyard the memorials to Mrs. SIDDONS, BANKS, NOLLEKENS, and HAYDON will in due course receive the attention they deserve and require. The Society has about 600 members.

THERE is a passage in the report of the Commissioners of Public Works in Ireland which suggests that as yet there has been no selection of a design for the Dublin Museum. It says:—"In response to the invitation issued by the Board, thirty-two sketch designs were sent in, which, having been referred to the committee of selection appointed by your lordships, five were selected therefrom in accordance with the terms of the competition, and the authors of these designs having submitted matured drawings for further critical examination, they were referred to the committee, whose report thereon is at present under your lordships' consideration." The report is dated May 31, 1884, and the inference to be derived from it is that there was nothing approaching a decision at the end of May. The announcement of the result of the competition in the Dublin newspapers was rather premature.

THE Conference on Water Supply by the Society of Arts, will be held at the Health Exhibition on Thursday and Friday in next week. The Conference will meet each day at 11 A.M., and will sit till 1.30, then adjourn till 2, and sit again till 5 P.M. The proceedings will be opened on Thursday, at 11, by the Chairman. The papers and discussions will be arranged under the following heads:—1. Sources of Supply. 2. Quality of Water; Filtration and Softening. 3. Methods of Distribution; modes of giving pressure; house fittings; discovery and prevention of waste, &c., &c. The proceedings will be continued on Friday, and if necessary on Saturday. The readers of papers will be restricted to twenty-five minutes. Speakers will be restricted to ten minutes. The papers to be read will, in most instances, be printed and distributed in the room. Members desiring to attend the Conference will be furnished with tickets admitting to the Exhibition and to the Conference room, on application to the Secretary of the Society of Arts, John Street, Adelphi.

THE Commissioners of Public Works in Ireland have during the past year sanctioned loans for the erection of labourers' dwellings, which amount to 40,052*l.*, or nearly double the amount lent in the year before. The loans for sanitary purposes amount to 188,035*l.*, and the total advances under the Act now amount to 949,619*l.* There has been a large demand, which is still increasing, for grants towards erecting new schools, and, though no expense is sanctioned in the erection of these schools but that which is necessary to secure sound construction and efficiency in working, the large number of cases involves a very considerable annual outlay. The great increase in the last few years is attributable to the removal of opposition to the placing of the schools under the National Education Board, and the extension of the system to remote districts. During the past year the Commissioners of National Education have notified grants in aid of building fifty-five new schools, and of structural alterations and improvements at forty-two others, and a considerable amount of work, for which grants were made in former years, has been carried out.

THE Council of the National Smoke Abatement Institution are able to report that satisfactory and encouraging progress has been made during the past year. Some of the largest bakeries have adopted the improved gas-heated and other modified furnaces, and are now working without producing any smoke whatever, and producing results eminently satisfactory. Gas engines, which are now used in various trades, have, in the case of engines up to 20-horse power, frequently proved themselves more economical than steam, as well as being completely free from smoke. The use of smokeless coal and coke for heating purposes, both domestic and industrial, has increased considerably during the past year, and the system of heating houses uniformly by hot-water pipes has also increased as the direct result of the improvement made in the apparatus. From the communications received from many places abroad as well as from all parts of the United Kingdom, the council are satisfied that the desire to abate the smoke of towns is fast increasing, and that the means of accomplishing that object have generally improved in kind and increased in variety.

## ILLUSTRATIONS.

PEMBURY END, TUNBRIDGE WELLS.

THE house which is a subject of illustration this week forms, with the stables and other erections and the entrance lodge, a group of buildings just approaching completion on a site having an area of about thirteen acres. It was the aim of the architect to produce a compact plan, and a good deal of care was taken, as will be apparent to architects on examination of the arrangements shown on the plan accompanying the illustration. The appellation given above may not be permanent, but it was found a convenient one during construction as indicating the locality, which is quite on the outskirts of Tunbridge Wells, and near the village of Pembury on the borderland of Kent and Sussex.

The style may be called Jacobean, and the material used is stone, the mullioned windows and copings being of Monk's Park Bath, and the walling generally, and a great part of the masonry being of local ferruginous sandstone, got from the deep beds of a quarry in the neighbourhood. The remarkable durability of this stone is evinced by a study of the thirteenth-century work of Tunbridge Castle and Bayham Abbey buildings, at the extreme ends of the district. In the latter building, now a ruin, the mouldings are exceedingly delicate, and the arrises still remain quite sharp-edged. The inner part of the walls is built of impervious bricks.

The tower, which becomes important in the view selected, was not part of the original design; but as the site is considerably elevated above its surroundings, and is 500 feet above the sea level, there was a strong desire to command a view of the surrounding panorama. The approach to the summit is by means of an easy circular stair, and the high parapets at each angle, with their glazed loopholes, serve as wind-guards for those who may like to sit and gaze on the spreading landscapes of Kent on the north and Sussex on the south.

The entrance archway face of the tower is nearly south, and the sun-dial is made to incline towards the west to catch the

rays which mark the later hours of the day. The dial with its gnomon was calculated and set out by the architect by the use of the terrestrial globe.

Messrs. COWLAND & Co., Portland Works, Notting Hill, and Queen's Road, Bayswater, were the contractors for the work, and a great degree of assiduous personal supervision was given to the work by Mr. C. D. COWLAND, the head of the firm, to whose energy at the quarry, and on the works, is greatly due the fact that the whole has been completed in the space of one year.

The perspective drawing was made by Mr. THOS. GARRATT, under Mr. CURZON's directions, and it may be worth while to point out that an experiment in the perspective of the tower has been introduced to meet an inevitable presentment, and, accordingly, in the drawing the tower diminishes upwards, which is not the case in reality.

SHOPS, ETC., DALE END AND JAMES WATT STREET BIRMINGHAM

THIS block of buildings is now in course of erection for Mr. ALFRED HUMPAGE, and provides premises for a tavern, commencing with the circular corner and extending up James Watt Street, and also for five shops and dwelling-houses in Dale End. The elevations will be executed with best red brick, with moulded and carved brickwork, and with Round Oak stone dressings. The shop fronts, bay windows, &c., are of wood, and will be painted and decorated. The roofs, top of bay windows, and top of shop front, will be covered with brindled tiles.

Mr. THOMAS GOUGH is erecting the buildings from designs by Mr. OLIVER ESSEX, A.R.I.B.A., of Birmingham, at a cost of about 5,000*l*.

CLIFTON STREET BOARD SCHOOLS, SWINDON.

THE design which we publish this week was selected in an open competition in which forty-six architects took part. The walls are of brick with stone dressings. The schools will provide accommodation for 600 children.

The contract has been let to Mr. BARRETT, builder, of Swindon. The architect of the buildings is Mr. W. H. READ, also of Swindon.

SKETCH IN BREDA.

THIS illustration, from a drawing by Mr. R. M. ROE, shows the great church and the most picturesque part of Breda in Holland.

## ARCHITECTS' CONFERENCE AT THE HEALTH EXHIBITION.

THE Conference of Architects met a second time on Friday, the 11th inst., Mr. J. Godwin in the chair, when papers were read as follows: by Mr. E. C. Robins, F.S.A., on "The Impermeable Construction of Roofs, Walls, and Basement Floors, with a Reference to Ventilation and Warming incidental thereto"; by Mr. J. P. Seddon on "The Construction of Chimneys." Mr. C. Forster Hayward, F.S.A., opened the discussion, on the termination of which Mr. Horace Jones read a paper entitled, "A Suggestion with regard to the Construction of Doors so as to afford opportunity of escape from Fire;" and another on "An economical mode of Fireproof Construction adopted in several instances in Public and Private Buildings."

The closing meeting of the Conference took place on Saturday, the 12th inst., Mr. Beresford Hope, M.P., presiding. Papers were read by Mr. George Aitchison, A.R.A., on "The Sanitary Aspect of Internal Fittings and Decoration;" by Mr. Wm. White, F.S.A., on "The Hygienic Value of Colour;" and by Mr. F. H. Watson on "The Collection, Storage, Management, and Distribution of Water, for Domestic Purposes, within the House."

A report of the proceedings will appear in next week's issue.

## DR. SCHLIEMANN'S DISCOVERY AT TIRYNS.

A CORRESPONDENT of the *Manchester Guardian* writes:—

Since I was able to make an early communication to you on Dr. Schliemann's extraordinary discovery of a vast prehistoric palace or castle at Tiryns, in the Peloponnese, fresh facts of great importance have come to light. From further excavations and closer inquiry it appears now that this remarkable building is even older than was thought at first. Its most archaic portions are now assigned to the thirteenth, perhaps even the fourteenth century before our era, whilst the later partly rebuilt portion is attributed to the eighth or seventh century B.C. In this way it would be of even higher antiquity as regards its first foundation than the heroic graves of Mycenæ, with which it was at first held to have been contemporaneous. The vestiges of a terrible fire by which the palace at Tiryns was destroyed are yet visible everywhere. A Viennese archæologist, Dr. Moritz Hoernes, who went to Tiryns with a recommendation to Dr. Schliemann, states that at the door and window openings the stone has been burnt into a chalk-like, the clay into a brick-like, mass. Otherwise the ruins are in a good condition. In that vast conflagration all the numerous wooden doors and roof columns, and the roof itself, disappeared; but the places of the columns are still discernible by slight circular elevations of the floor. From another source we learn that the bases of twenty-seven columns, formed of hard limestone, have been found; also a most ancient Doric capital. Dr. Hoernes reports that near the gate "the Cyclopean circumvallation still overtops the castle, and that there, in the narrowness of the gloomy gateway, the masses of stone, heaped up on all sides, are doubly impressive to the eye. At this place the onlooker gets a truly overpowering sensation of the whole prehistoric settlement. A feeling is created that we are

here on the threshold of an architectural development which forms a transition to the Lion Gate of Mycenæ, so that the latter archaic work, though it gives rise to such wonderment, already appears to be something more recent and more refined." Near the threshold of each room, Dr. Hoernes continues, the bases of two columns as well as the faucet holes of the folding doors, are still to be observed, both columns and doors having been of wood. In a large ante-room there is a square structure, to which steps lead up from the door. Dr. Schliemann holds it to be an altar of the house-protecting chief deity (Zeus Herkeios), in accordance with the custom mentioned in Homer. A great many walls, divided by intervening walls, evidently formed at first a single hall—a throne-room, as the phrase would be now. In the centre of this splendid room there is a large circular cut in the floor, with four bases of columns set in a square. Dr. Hoernes considers it a "mysterious contrivance." May it not have been a seat for a king, or a receptacle of house-gods? Under the western wing of the hall there is a bath-room, proved to be such by a large stone slab at the bottom, and by a still well-preserved waste-pipe. Whatever remnants there are of wall paintings are very fresh in colour, of strikingly bright and gay tints. From a communication made by Dr. Schliemann to the Anthropological Society at Berlin, we gather that the colours used are black, red, blue, yellow, and white. One of the wall paintings, according to Dr. Hoernes, represents a bull in full career. On its back a small nude male figure is to be seen, agitating itself in curious fashion as if engaged in some acrobatic performance. The proportions of the bull are faultlessly rendered, the details given with naturalistic fidelity; the movement of the human figure is most exaggerated, almost as if it were on the wing. The background is dark red; the bull yellow; the human figure white. Seeing how exceedingly rare any mural paintings of Greece are, these archaic pictures are of incalculable value. A mass of pottery and terra-cotta figures, many of them of extraordinary freshness, were contained in a large number of baskets when Dr. Hoernes recently inspected the ruins. He also mentions some slabs of alabaster, with relief sculptures—sparse remnants of a once splendid inner decoration of the rooms. Many knives of obsidian, and rudely-formed hammers of diorite and speckled marble have been found; little metal, no iron, but a great deal of lead. Of interest also is the discovery of charred grains which, after a close investigation by Prof. Wittmack, have been recognised as the remnants of grapes. At the foot of the rock on which the castle stands Dr. Schliemann has discovered Cyclopean house walls. Here there must once have been the dwelling-places of a rural population, "seeking shelter under the castle like a herd near the herdsman," to use the words of Dr. Hoernes. Besides these pre-historic discoveries, Dr. Schliemann found the ruins of a Christian church from Byzantine times—probably from the sixth century. Within and without it many graves have been opened, the contents of which promise important results for ethnology, skulls and bones from that century being as yet exceedingly rare.

## DRAINAGE UNDER DWELLINGS.\*

BY S. FLINT CLARKSON.

SOME very simple things may be said naturally, if addressed to a resident in a good-sized house in a large British town, who wishes to learn how the appliances for drainage, shown in this exhibition, are used. It will be easy to begin at the beginning in everything; and pleasant to fancy that he begins to learn now, because he has not been to an International Health Exhibition before, and not because he is dense or heedless. Usually bitter experience has taught the well-to-do householder some lessons; people who have suffered in health, purse, and temper by bad drainage do not need much looking for. In the next generation we hope some searching out will be necessary. What is being done now is not all perfect, either in system or execution, but it may fairly be assumed that the best work of the present time will pass muster well for many years.

However desirable it would be to avoid drains under dwellings altogether, back drainage is impossible very frequently for terrace houses—those houses put close together, which will always line streets in the central portions of our towns. The sewers are in the streets, and the water-closets and sinks are where they must be, or where they happen to have settled themselves—most often at the back. Anything which is desirable for other drains, in less important places, may be considered absolutely necessary for those under dwellings, which should, of course, be as near perfection as possible.

1. *What to avoid.*—By pointing out briefly the bad qualities of brick drains, such as used to carry away the refuse matters from dwellings, what are good qualities in drains generally may be perceived without an effort. New brick drains are rarely constructed nowadays, but plenty still exist under and round about houses; so that they are not as yet mere matters of antiquarian interest. We will hope that all here will live to see a bit of the

last example put into a museum. The special sub-committee who have devised the insanitary house in the central avenue have judiciously decided to show only the usual defects, not exaggerating the ordinary conditions. A special pamphlet and a good show of special labels and diagrams will help—almost force—everyone to see those defects. If they had exposed to reprobation anything practically obsolete, for the sake of the effective contrast of a very bad system, very badly carried out, with a good system, they would—doing it on such a scale and in such a permanent form—have been inartistic. For showing up persons or things with much effect human nature insists upon the facts of the current hour being kept to very closely, and rebels if there is a call to hear of, or look twice into, an offence not committed yesterday or to-day. In a slight address, in which brevity is all-important, an awful warning is less out of place.

In brick drains (and in drains of rubble stone equally) the materials were porous—absorbing liquid foulness, and giving it out in foul air when stirred, half dry, or dry. The bottoms were too frequently of bricks laid flat in mortar; the bricks grew loose, and the bed of the channel became a row of little cesspits. In true barrel-drains the round bottom was usually covered with cement, but it was applied with difficulty, and frequently not very smooth. With any slight disturbances the coating cracked, parts peeled off without anybody knowing where—renewal was out of the question. There were thus always little pools above the porous bricks. Rats worked their way between flat covers and side walls, or enlarged any crack in a barrel. The bad air in the drain found its way into the building, and the rats too. With bricks, barrels were not made less than nine inches diameter, which we know is too large for an ordinary house-drain. Little streams of water turned through large flat-bottomed drains were shallow and slow; and in nine-inch barrels, with rough insides, there was but little improvement. The solid matter was left behind by the liquids; flushing applied with the most extreme rigour could not cleanse such drains. They were (1) of porous materials; (2) not smooth inside; (3) with joints too frequent, and soon becoming imperfect; (4) too large; (5) difficult to cleanse.

No intelligent and careful use of the materials could get rid of most of these defects. The drains were, however, frequently laid with very little fall, (6) and this might have been different. But fall was often not easily got; at the upper end the top of the drain was quite close to the surface, and the whole fall in 90 or 100 feet was next to nothing, varied by falls the wrong way. No swift rush of water seeking a lower level took place, and the drains became in time long cesspools. They were also (7) often in direct communication with the common sewer, without the interposition of a trap; there was then a constant supply of foul air from foul sewers to the house drains. The drains were not ventilated (8). Perhaps a dip trap of brick and stone—a little cesspool in itself—tried to cut off the direct connection with the sewer; but in all the pipes discharging into the house drains, there were water traps and no open ends—no induct or exhaust pipe. The drains were left to themselves with the utmost determination, and a faint hope that they would behave themselves decently. No attempt was made to change the air in them by passing fresh currents through. The foul air took its own course. Holes were eaten in lead pipes and traps, and vents made; and rushes of air took place at open joints, at imperfectly trapped sinks, and whenever waterclosets were flushed.

2. *Stoneware Drains.*—With a good system of drainage, everything generated in the house of an offensive and injurious character will be removed as fast as it is produced, and the drains will be watertight, clean, and full of fresh air. All the eight defects noted above may be avoided if good stoneware pipes are used as they should be. They are manufactured in many places in the United Kingdom and are not expensive, not nearly so costly as brick drains cemented inside would be. Well-burnt, hard, glazed stoneware pipes absorb no moisture; the vitrified glaze renders them as non-porous (1) as an old-fashioned brown drinking-mug; they do not corrode; they are quite smooth inside (2); once well cleansed the surface is what it was at first.

The fewer the joints the more perfect the drain. If one could be put down all in one piece we should do well, but nature has apparently not arranged for this. In the stoneware drains joints occur at every two feet, and if properly made they are very lasting (3). [These numbers are those of the defects in the brick drains noted above; the contrast is thus pointed out, and the way in which a defect is overcome.] The length of 2 feet is convenient for making, firing, conveying, and handling. A length of 4-inch pipe weighs about 15 lbs., and a length of 6-inch about 26 lbs. In each batch of pipes there are failures which must be cast aside; they should never be sent out from the works. They may be of insufficient thickness, rough on their surfaces, too brittle, fired too much or too little, not truly cylindrical, or otherwise defective in form. The pipes are made thicker as the diameter is increased. A 4-inch pipe is  $\frac{3}{8}$  inch or  $\frac{1}{2}$  inch thick; a 6-inch,  $\frac{3}{8}$  inch; a 12-inch, 1 inch. If too thin or brittle, the broken pipes will saturate the soil around them with foul matter; if rough on the surface, obstructions will occur; in either case the drain will be blocked up. If they are not truly cylindrical in form (or not truly oval in the case of oval pipes), one pipe will stand above another at the joint and

\* A paper read at the Conference of Architects at the International Health Exhibition.

stop the flow. An ordinary pipe is constructed with a projecting rim or socket at one end—a faucet into which the plain end of the next pipe fits as a spigot. The inside of the faucet and the outside of the spigot have parallel grooves to give a key to the material introduced to form the joint.

The lowest pipe is laid first, with the socket at the highest end. The plain end of the next pipe is placed in that socket, and the space between it and the socket is filled in with a mixture of cement and sand. Clay should not be used for drains under dwellings; there the joints should be as air and watertight and as indestructible as possible. Before the cement has had time to harden the interior of the pipe is wiped out very carefully. If this is not thoroughly done, a ridge or small lumps of cement will stick up at the joint. Long hairs, threads, pieces of cloth, or cotton stuff will attach themselves to such projection; soil will then cling, and a stoppage be managed sooner or later. To guard against such ridges or knots, joints have been treated somewhat as in iron water-mains; that is to say, strands of gaskin have been put round the upper pipe, so as to make it fit tightly in the socket, and then cement packing, put to fill up the rest of the socket, cannot reach the interiors of the pipes. Some lodgment results, however, and consequent imperfect cleansing, if the whole space between the two pipes is not solidly filled up with something as hard, or nearly as hard, as the pipes themselves.

A careful and skilful workman, taking a pride in his work, does a good many things and avoids a good many others, in the apparently so simple work of laying a pipe-drain. An unfitted joint, or one imperfectly fitted, or fitted with improper cementing material, is as troublesome as one from which the luting has been allowed to protrude. Nothing is more desirable than the recognition of care and skill, and the fostering by every means of an honourable pride in the workmen employed in drainage work, and frequently working in dirty holes, in darkness or semi-darkness, disturbed times and again by the passing of other workmen and of materials, driven perhaps by an exacting or ill-tempered foreman, responding to the demands for quicker progress from an employer, rendered desperate by a proprietor to whom a poisoned goad has, it may be, been deftly applied at his domestic hearth. The temptation to think only of quantity without heeding quality must be strong at such times; average human nature is not abjectly subject to duty. The absence of special training should be remembered also in extenuation of faults. In times of pressure on the cheaper kinds of work, a strong, decently intelligent labourer has been known to leave pickaxe and shovel for a day or two and lay drains with a will. Special training, plenty of supervision and good lighting, should not be wanting for every length of good pipe that is laid. There should also be a general disposition to haste without hurry, and some special sign of appreciation from someone when all is found correct at the end.

Invention is always at work suggesting modifications in the form of pipes, but the whole-socket pipes hold their own as yet. By using half-socket pipes every alternate pipe can be removed without breaking any pipes for inspection of the interior of the drain, or for the insertion of a junction to receive a new drain; but it will be readily seen that a gain is balanced by a loss. Sockets are sometimes dispensed with entirely. Broad chairs of stoneware, each five sides of a decagon externally, are first set down, and the pipes are laid and bedded upon these chairs. When the whole have been inspected and tested, saddle-covers are put in their places, with soft clay under them. Any saddle can be readily removed for inspection, or putting in a saddle junction. Reasonable people do not demand a new junction very frequently, and for drains under dwellings, which are best thoroughly sealed up, no contrivance for the occasional removal of bits of pipes is in much favour. They may be useful at times elsewhere, but further mention of them may be omitted for the moment.

When Stanford's Patent Joint is used, skill and love of thoroughness will be of service in the workman who lays them, albeit the attempt is made to produce pipes requiring no skilled labour in the laying. The spigot ends of the pipes are trimmed, so as to prepare those not precisely accurate in form for receiving a perfect ring cast in a mould. The socket receives chipping, and a ring is cast on to it also. These rings are spherical in section, and the fit thus resembles that of a ball and socket joint. The spigots and sockets are wiped clean, the sockets oiled, the pipes placed in position, and gentle blows from a wooden mallet send the upper pipe into its place; by a peculiar sound the workman knows when it is "home." Of course the preparation of the bed is very important still, and the keeping of line and level; besides the joints may be badly moulded on the spot, or chipped and damaged in transport if supplied on the pipes; the spigot pipe may not be driven properly home, or mud splashings may be left on the joints. There are other special joints, but it is only possible to touch lightly on jointing, or indeed on any other division of the subject. After giving a little insight into general principles, inquiry into the merits or demerits of particular methods of inventions must be left alone.

Stoneware drains are ordinarily made in all sizes from 1½ inches to 24 inches in diameter. They can thus be obtained (4) of sizes not too large for house drains, and can be easily flushed and cleaned (5). For families of any size the main drains

are usually 6 inches in diameter, and the branch drains 4 inches. As the rate of flow in any pipe—the fall remaining the same—is quickened by narrowing the pipe, and thus deepening the stream, any excess of size is really prejudicial.

3. *Some Defects in Stoneware Drains.*—When pipes are ordered hurriedly and arrive too late, there is sometimes a wish to use those which have come, and not to wait further for the special pipes which ought to have been ordered before. When the changes cannot be made at the junctions, pipes of one diameter should always be joined to pipes of another diameter by diminishing pipes and in no other way. Patched junctions are painful shows of inefficiency; obstruction comes sooner or later when the filling-up breaks down into the pipe. Right-angled junctions cause trouble; a branch should discharge through a junction at an angle approaching the line of flow of the drain which is entered. When bends are required, but have not been supplied, straight pipes will be used with apologies, "so as to get the work done," unless there is interference. If the curve is of short radius the spigot ends will actually leave the sockets on their outer sides. Speaking generally, very bad stoneware drains will be of porous pipes, rough in their insides, broken and pieced with cement; some joints gaping, others leaking; some badly made with bad cement, some with projections of the cement inside; not sealed over; laid to curved and irregular lines, with right-angled junctions; the curves made of straight pipes, without diminishing pieces at change of size, and occasionally with larger pipes inserted in the run of smaller ones; without inspection chambers; put on new made or yielding ground; in parts running uphill, and the rest laid to flat and irregular gradients.

4. *Iron Pipes and Subways.*—Some architects, in certain parts of their best work, use iron pipes with yarn and lead joints, similar to those in water-mains, in preference to any stoneware drains. In Paris they are always used—not buried in the ground, but exposed to view. In America they are common, and compulsory in some places for drains under dwellings. They are enamelled inside, or treated by the Bower-Barff (rustless iron) process. Mr. John J. Stevenson, the architect of the new mansions at Kensington Court, has taken great pains there, and used all the most modern sanitary appliances. He has kindly lent me a drawing showing the system pursued. Heavy cast-iron pipes, 5 inches diameter, are laid in perfectly straight lines under the houses. They are lined with Dr. Angus Smith's composition, a preparation of tar, which gives a smooth and apparently indestructible surface. Joints occur at every 6 feet, and are thus one-third of the number in a stoneware drain; there are no difficulties with defective cement or the careless use of it. Being much more costly than stoneware pipes, the iron pipes are only used immediately under the houses.

Similar iron pipes were put by Mr. E. C. Robins on wall brackets in a subway—a kind of sub-basement—in the Museum of Building Appliances, in Maddox Street, Regent Street. This sub-basement is a sort of passage about 4 feet wide and 7 feet high, the floor 16 feet under the street level. Air is admitted to it from the area next the street, and there is a good sized shaft at the back about 30 feet in height above the floor. Other pipes are placed in the subway as well as the iron drain, and fresh air led from it to supply the rooms throughout the building. The use of subways under the basement storeys of London houses was advocated some years ago by Professor Kerr. He placed "an annexe at the back of the house to contain all the water-closets, the bath-rooms, all cisterns, and the housemaids' sinks, and draw-off taps. A vertical shaft within the annexe would run from the basement floor to the roof with an escape for air at the top. This shaft would accommodate all vertical pipes—water-pipes up and down, wastes, soil-pipes, gas-pipes, the heating circulation, perhaps the rain water-pipe, and the ventilation of the kitchen, and perhaps of the principal rooms might be accomplished by its means. The subway would contain all the horizontal continuations of the pipes from the shaft to the street, and also the house-drains. It would extend from the usual open area in front of the house to an open area at the back, and at each end there would be a manhole for access."

5. *Lines and Levels.*—Subways are luxuries which cannot be afforded every day. We will go back to stoneware pipes, with the remark that good materials, put together properly, must be put in the right place. Long straight lines are always preferable. It is more easy to get the levels right, and to see that they are so; there are no checks to the flow, which is a very important point with water-borne solid matter; they can be more readily tested at first, and from time to time, and more readily unstopped. For a drain under a dwelling it is indispensable that it shall run in one straight line from the point at which it enters to that at which it leaves, and for a few feet more at each end.

At the junction of the straight lengths of the pipe drains, and at any bends, small inspection chambers are put; at the bottom of these a length of half-pipe forms the channel. When the cover is off, the character of the flow of the drain is seen at once. Brickwork is carried up above the line of flow. The stone cover of the pit is bedded in mortar, and the joint round it pointed at the surface with cement. These are only opened when defects are supposed to exist, or when special cleansing of the drains is to be undertaken.

Having determined the lines which the drains are to follow, it is then necessary to settle the inclinations at which they shall be laid, in order that they may convey all effete matter quickly to the sewers, and be self-cleansing. Of course if there was too much fall, and the slightest check, the solids would remain and the water run away. But too much fall is the rarest thing; not being able to get enough is what we are wont to grumble about. The fall is strictly limited by the depth of the sewer below the lowest floor, and the necessity of keeping the drain well under the floor at the upper end; 2 feet under the finished floor is considered desirable, though we have sometimes to make ourselves contented with less. The least fall approved for 6-inch drains is 1 in 40, that is 3 inches fall in each 10 feet of horizontal distance. More is valued if it can be managed, certainly 4-inch drains should have more. It is desirable to have a flow of at least 150 feet per minute with a shallow stream of water. When drains are laid to flat gradients some special means of flushing them must be used daily.

If the pipes are laid upon yielding ground they will not keep level; some will tip one way and some another, the joints will snap, and sometimes the pipes also, resulting in hills and dales, leaking joints and stoppages. It is so easy to be wrong. Too much earth is taken out in parts of the trench, and some of it filled back, and the ramming perfunctorily done, or nature may have interposed little pieces of yielding stuff between pieces of solid. A bed of cement concrete, carefully levelled on the top to the proper fall—a bed of artificial rock in fact—laid along the whole length, will give the pipes a fair chance. In this concrete grooves will be made to receive the lower parts of the pipe-sockets, and the whole of the length of each pipe will then rest on an immovable bed.

Refilling the trench must be managed without disturbing the pipes. The hollows under them being very carefully filled up with concrete, it must also be put at the side of the pipes, with a thickness of 6 inches on each side, and then 6 inches over the top. Such a covering of cement concrete is usually stipulated for in byelaws for drains under dwellings, sealing up the pipes altogether as an additional precaution against evil results from defective jointing. It also serves to protect the pipes from displacement by impact on the surfaces above them.

**6. Disconnection from Sewer; Ventilation; Connection with Sewer.**—After the house-drain has left the house, and before it reaches the sewer, a break is made, and the drain runs past an open space. On the side of this air-space, next the sewer, is a water-trap with a good seal, intended to prevent any bad air in the sewer from reaching the air-space. If, however, this trap is neglected, or pressed upon a good deal from the sewer, tainted air will not enter the house, but will find its way out of the air-space. From the air-space fresh air enters the drains under the house, and a current is kept constantly moving through them by arranging ventilating pipes at the higher ends, which shall run up to the top of the building.

Some disconnecting traps are large shaped pieces of stoneware, which shut off the sewer at one end, and receive the house-drains at the other. A pipe carried up at the house end supplies the fresh air above the trap, when a grating at the surface of the pavement is objected to. With other traps the construction of a man-hole is contemplated. This is a little chamber built up under the pavement of an area, through which the drainage is carried in half-pipes of enamelled ware. The trap is a syphon or U trap put on the side of the manhole next the sewer. A grating at the surface is sometimes put when there is plenty of space; more usually a flue is constructed and filled in with a ventilator having small mica valves, which rise to admit air into the flue, but refuse to let the air come out. In time of storm there might be a set in the wrong direction—the long upright pipe at the back of the building might carry a rush of air downwards, and it would find vent at the induct and cause annoyance. Protected by these mica valves, the flue is unsuspect, and a moment of rest allows the pent-up air to go upwards according to its want. The manhole makes inspection of the drains easy; an air-tight iron cover is often put over it.

The ventilating pipes, at the upper ends of the house drains, are of lead or of galvanised cast iron, well caulked at the joints, and all four inches in diameter, or as large as the branches they start from. The soil pipe serving the water-closet is usually extended upwards; being joined at its foot to the house drains without any trap, a current of air passes steadily through drains and pipes. Long branches must have special ventilating pipes; short ones will be cleared of air by the discharges, and supplied with freshened air from the main drain. These upcast exhaust pipes must not finish near windows or cisterns, nor be stopped at the eaves, so that they discharge under the open joints of slating; nor must they stop just above the tops of chimney flues, nor be carried into the flues themselves. If they are, bad air will reach the insides of rooms. Wires, or a perforated finial, must be put to keep out birds, or an approved cowl.

The drain should be connected with the sewer in the upper half, above the line of flow, at the haunch just above the springing. The custom at one time was to put the mouths of the house drains below the water-level in the sewers, but this is given up

now; the intention was to prevent sewer air entering the drains. Connections must join the sewers obliquely in the direction of the line of flow of the sewer. The pipe sewer junction blocks, invented by Mr. Cockrill, are a considerable improvement. Oblique junction blocks and bends are used for brick sewers. Flap-traps are railed at and still used. The hinged valve allows a passage out from the house drain, but not into it; the flap closes by its own weight when the flow has passed through.

**7. Inspection, Flushing and Cleaning.**—Other connections with house drains for sinks, baths, rain water pipes, &c., the traps to them, and the ventilation of pipes and traps, form a branch of our subject, not forgotten but very extensive. The construction, maintenance, cleansing, and the efficient ventilation of sewers might seem another branch. Everybody is interested in it, architects specially so. It is well, however, for everybody to have his own province, and do the best he can in it, and architects are content with a province which extends, in large towns, as far as the walls of the sewers, but not beyond.

When the drains are completed, disconnected, connected and ventilated, they must be examined keenly before they are used, so that if by chance there are defects they may be remedied. If the lower end of the house drain is plugged and the pipes are filled with water and left for a few hours, and the level of the water in the testing bend has not sunk, it has been proved that pipes and joints are sound, that there are no vents for bad air, or cracks through which moisture will run away. The levels of straight drains can be tested by actual measurement, and the effectiveness of the gradient proved by floating down something in a good flush, and noting the time. At cast-iron terminals, with air-tight brass plugs placed in a back area at the upper end of a drain, various tests for soundness and level can easily be applied. With drains in use, water mixed with lime is poured in at the end. By the amount and character of the discolouration of the effluent water, before and after flushing, the condition of the insides of the pipes will be judged.

The beautiful arrangement shown by Mr. Hawksley (470, Class 22) for testing house-drains and soil-pipes with a plumber's force-pump and gas-pressure gauges, shows when there is any leakage, and localises the leakage too. The traps act as plugs; the ventilating pipes, and the end of the house-drain next the disconnecting trap, must be thoroughly plugged up. The smoke test calls attention to important defects; little holes may, it is true, be plugged up by some chance at the moment when the test is applied. Straw burnt in the drain may send smoke all along it, or smoke may be generated in a vessel and forced in by a machine. These appeal mainly to the sight. The peppermint test—a favourite one on account of the ease with which it is applied—appeals to the sense of smell, as does sulphur burnt in a shovel at the mouth of the disconnection chamber. Ether, oil of mint, and other strong smells have been suggested.

The difficulty in active life is in getting anybody to look for defects periodically. Detection is disagreeable for one thing; afterwards there is the remedy, which seems not worse than the disease it may be, but unpleasant and worrying. Mr. George Godwin, one of the honoured pioneers of all sanitary improvements, an architect who, forty years ago, showed the way in which all the world is now prepared to walk, pointed out constantly that "good health shows good sense; that the laws of nature have been understood and attended to." This, in the present connection, would mean that if a householder cannot get his servants to look after the drains at proper intervals, he had better employ a sanitary association or some one else to do so. The same thing might have been said of flushing years ago, but self-acting flushing tanks now do that work without being looked after. All that is necessary is to set a tap to run a small stream, and the drains will be scoured by the sudden rush of a number of gallons of water at the required intervals. Thirty or fifty gallons liberated so that the 6-inch drains are at least half full clears away obstacles, and cleanses the surfaces of the pipes. Large flushes may indeed, if applied too frequently, damage the pipes by washing away the cement from the joints. It is well to be somewhat moderate in the use, except where the drains have little fall; then a daily flush is indispensable. The supply of air to all traps must be well provided for with these flushing arrangements, or the rush will syphon out the water from them.

The fine sand used in scouring metal behaves awkwardly in a drain, and grease is a positive terror. The amount of energetic invention expended on grease taps should appeal to every visitor to the exhibition. Even with good flushing, occasional cleansing by absolute scraping and brushing is desirable. It ought to be set about at once when there are indications of trouble in the air. Traps and bends and branch drains should not be allowed to get wrong, but looked to from time to time. By bundles of screw-jointed canes any distance may be reached, and obstacles removed by means of rakes, balls, rollers, and brushes with comparative ease from drains laid in straight lines and to regular falls. Put shortly, all that is necessary for starting drains properly and keeping them right is to use the right materials and put them together in the right way—in straight lines with proper falls, and to send plenty of water and fresh air through them.

## THE PARKES MUSEUM.

AT the annual meeting held July 9, Captain Douglas Galton in the chair, a letter was read from the Duke of Westminster regretting his inability to attend the meeting, and a report was read by the chairman of Council showing the valuable work that had been carried out by the museum during the past year.

Twenty-one lectures have been arranged by the Council and delivered in the museum by some of the best authorities on Hygiene and Sanitary Science. These lectures have contained much valuable information, and have dealt with a majority of the subjects included in the scope of the museum in a most useful and interesting manner.

The museum has been largely used by lecturers on Public Health and other skilled teachers, for practical demonstrations to various classes of students, &c., who for this purpose have been admitted to the museum without entrance fee. In this way the special advantages offered by the museum have been utilised for the purpose of instructing a large number of students and others who, by the nature of their several callings, may be expected in various ways to exercise an important influence in the promotion of health in connection with the construction of dwellings and otherwise; and the Council are glad to report that the facilities thus offered have been fully appreciated, both teachers and students having expressed a desire that further opportunities of the same sort might be afforded them. The members numbered ninety-nine on June 30, 1883, just after the opening of the museum. They now number 260.

During the year the museum has been visited by 6,870 people.

The utility of the museum has increased month by month. The museum has clearly met a great public want, and the Council would again strongly urge upon the members, and upon all who are interested in sanitation, to use their personal influence so to increase the number of members and life members that the future of so valuable an institution may no longer be a matter of doubt.

## TEXTILE FABRICS.\*

BY WILLIAM MORRIS.

THE subject I have to speak on is a sufficiently wide one, and I can do little more than hint at points of interest in it for your further thought and consideration; all the more as I think I shall be right in supposing that except for anyone who may be present being actually engaged in their manufacture, you have very little idea as to how a piece of cloth is made, and not much as to the characteristic differences between the manufactures of diverse periods.

However, one limitation to my subject I will at once state. I am going to treat it as an artist and archæologist, not as a manufacturer, as we call it; that is, I shall be considering the wares in question from the point of view of their usefulness, using the word in its widest sense, to the consumer, and not as marketable articles as subject-matter for exchange. I must assume that the goods I am speaking of were made primarily for use, and only secondarily for sale; that, you see, will limit me to an historical discourse on textile fabrics, since at present those wares, like all other wares of civilised countries, are made primarily for sale and only secondarily for use.

Now, before I begin to speak of the actual history of this important art of weaving, I will run through the various forms of it which it comprises. But first of all it may be necessary to explain the two words which I shall be compelled to use, because I have noticed that the writers of leading articles and poetry are sometimes a little vague about the way they use these words. Well, the warp is the set of strained threads (sometimes vertical, sometimes horizontal) on which the work is founded; the weft is the thread which is *waved* in and out across this warp, and the woof or web is the product of the two. I think I may explain any other words of this sort as they are used.

Well, first there is plain weaving in its simplest form, where the weft crosses the warp regularly and alternately; of that I need say no more, because I have to speak mostly of the characteristic ornament of the different periods, and this plain weaving is not susceptible of ornament—woven ornament I mean. To obtain that the weft must cross the warp at regular intervals, but not alternately; on the surface either warp or weft must predominate to make a pattern.

To speak broadly, in the most ordinary kind of pattern-weaving the threads come to the surface in a regular and mechanical manner. I have not time to explain all the ways in which this is done, but must ask you to accept that simple statement and allow me to call this kind common-figure weaving. Sometimes, as a sub-division of this common figure-weaving, the warp comes chiefly to the surface, which makes a satin; and also sometimes these warp-threads are caught up over wires with a sharp edge, which

are pulled out as the work goes on, leaving a surface with a raised pile, that is velvet.

In the next kind of weaving, the weft crosses the warp alternately indeed, as in plain, unpatterned weaving, but instead of being carried in one stroke, all across the web, ends or returns wherever the colour changes, so forming a kind of Mosaic of coloured patches; this is tapestry, using the word in its narrowest sense: as a detail of this work I ought to mention that in tapestry-weaving the weft is put in so loosely, and driven home so carefully, that the warp is entirely hidden by the weft.

That work may be considered as a subdivision of this kind of weaving where thrums of wool, hair, or silk are knotted into a plain canvas as the work proceeds, so as to form a pile with their cut ends: this is carpet weaving.

Lastly comes a kind of ornamental web in which the ornament is not produced by weaving, but by painting by hand or printing, combined with dyeing (in various ways) in the piece, printed goods, chintzes, and so on. Needle-worked embroidery may be considered as another way of ornamenting a cloth. How all these manners of weaving have been practised from time immemorial, and are in use to-day, with no more variation of method than what comes from the application of machinery for lifting up the threads of the warp, as in the Jacquard machine, now universally used in civilised countries, and the use of steam power for throwing the shuttle—these variations of method are of little or no interest from the artistic point of view, and are only used to get more profit out of the production of the ways. They are incidental and not essential.

However, ancient as all these methods are, the oldest way of ornamenting a cloth otherwise than by merely painting on it with a pigment, not dyeing or by embroidery, must have been the tapestry method, as it requires but a very small amount of technical skill. The figured webs of the Homeric poems were probably of this kind of work. In the British Museum there is a scrap of cloth of the ancient Central American civilisation so woven; the patterned cloths of the North of Europe before the fourteenth century were mostly tapestries; the South Kensington Museum has a precious fragment of such work of the eleventh or early twelfth century. Among peoples of higher industrial skill, the common figure-weaving took the place of this rude work for ordinary recurring patterns, but tapestry was still used for producing what may fairly be called woven pictures, webs whose elaboration and want of repetition of pattern would scarcely allow of any reasonable effect being produced by mere mechanical weaving.

The painting or printing of cloths is doubtless a very ancient practice, I mean to say the painting them with dyes, not pigments. The minute and elaborate figure ornament which is shown on some of the Egyptian sculpture has to me a look of being done by means of this art. It is a confirmation of this probability that Pliny, in a now famous passage, notices the fact that Egypt in his day practised a certain art of figuring cloth, his description of which leaves no doubt that it was what we should now call madder printing or painting. Of this art, I shall have to speak in the notice of dyeing, which will conclude this lecture.

So here we have to consider, to leave out plain unornamental weaving—1st. Common or mechanical weaving, including satin, damask, and velvet; 2nd. Tapestry, including carpet weaving; and 3rd. Painting or printing with dyes.

Let us consider, briefly, the practical history of these three arts. And first the mechanical or common weaving. With wares so perishable as woven cloth, it is not wonderful that we have little real record of the stuffs of antiquity, because the descriptions of the poets and writers of the time cannot be depended on for accuracy, as they of course assumed a general knowledge in their audience of the articles described. The pictured art of the Central Greek period gives us at all events some idea of the quality of the stuffs worn at the period, and, in so doing, fully confirm the beautiful and simple description of the fine garment in the "Odyssey," which is likened to the inner skin of an onion; a figure of speech which, taken with the representations of delicate cloth in the figure-work of the time of Pericles, and earlier and later, gives one an idea of something like those mixed-fabrics of silk and cotton which are still made in Greece and Anatolia; only you must remember that the early classical peoples at least did not know of either silk or cotton, so that flax was probably the material of these fine garments, and we know by the evidence of the Egyptian tombs that linen was woven there of the utmost delicacy and fineness.

I don't suppose we need doubt that mechanical pattern weaving was practised by the Greeks in their earlier and palmy days; but only I fancy for the simpler kinds of patterns in piece goods, diapers, and so forth. I conclude the running borders to have been needle-work, or may be dyed painting. We have a few representations of looms to help us in looking into this matter which, however, do not prove much: they are all vertical, and at first sight look nearly like the looms used throughout the Middle Ages, and to-day at the Gobelins for tapestry-weaving. In one which is figured in a tomb at Beni Hassan, in Egypt, the details of an ordinary high-warp tapestry-loom are all given accurately; but the weavers seem to be weaving nothing but plain cloth; in this loom the cloth is being worked downwards as in the ordinary tapestry-loom.

\* A paper read at a Conference at the International Health Exhibition.

In another representation taken from a Greek vase of about 400 B.C., Penelope is seated before her famous web, which is being worked in an upright loom; there is only one beam to it, the cloth-beam, and the work is woven upward. The warps are kept at the stretch at the bottom by weights looking too small to be effective: the web is figured, has a border of the ordinary subsidiary patterns of classical art, and a stripe of monsters on a winged human figure. It seems to have been concluded that this represents actual tapestry weaving; but too hastily, perhaps, as the high-warp loom only means a certain amount of inconvenience in foregoing the mechanical advantages of the spring-staves worked by treadles; also this Greek loom of 400 B.C. is in all respects like the looms in use in Iceland and the Faroes within the last sixty years for weaving ordinary cloth, plain or chequered.

So much, and little enough, of the loom-work of the early classical period, a time when the merely industrial arts, which were, you must remember, mostly carried out by slave labour were despised; when private luxury scarcely existed; a fact most happy both for the decency of general life and the glory of the arts.

Doubtless the ingenuity of the industrial arts gained much during the later and Imperial days of Rome; but there is little direct evidence in the remains artistic or literary of the time itself, Pliny, who is very particular on the subject of dyeing, helping us nothing in the matter of weaving. However, perishable as the actual woven wares are, the art is particularly conservative in design, and when we get nearer to our own epoch we have a certain number of specimens preserved to us from the tenth century downward, which not only show us how people wove in those days, but give us more than a hint of the fashions of centuries before their time. A very small fragment of cloth found at Sitten in Switzerland, gives us doubtless a type of a late Roman figured stuff: the pattern which repeats in a smallish space is of a woman seated on a fish-tailed form leopard-headed amongst conventional foliage; the point of it as an illustration of our history being that it is designed wholly in the classical manner, so that whatever the date may be, it is absolute evidence as far as it goes of the kind of work of the later classical times.

However, it is now time for us to leave this somewhat barren desert of vague poetical descriptions, hasty and generalised drawings on vases or tombs, and very rare scraps of the woven goods themselves, and march into the more fruitful country of the early Middle Ages, which give us quite direct evidence of the arts of weaving of the days of the Byzantine Empire. Now you must remember that whatever share the city of New Rome took in actually producing works of industrial arts under her Emperors, she was at least the *foster mother* of those arts for all Mediæval Europe, and from her came that influence which brought about the new art of Europe, whose origins are obscure enough till they met and fused at Constantinople into a style which for centuries after was world-wide: this was natural enough. Looked upon as an European city, Byzantium was for long the only great city of Europe that was really alive and dominant; in peace and war, as a mistress or an enemy, she dealt with all the great birth-countries of art and letters, nay of human life. India, Mesopotamia, Syria, Persia, Asia Minor, Egypt—the ideas and arts of all these countries touched her and mingled with the remains of the older art of Greece, from which the academicalism of the long Romano-Greek period had not crushed out all the life, sorely as it had weighed upon it. Byzantium, then, the Byzantium of Justinian and onwards, we must look upon as the capital of the industrial arts from the sixth to the thirteenth century, and in none of them was her influence more obvious than in that of weaving. One event alone which took place there revolutionised this art in Europe, the introduction of silk in the sixth century, which event has also made it more possible to judge of what was done in early times, because the material having the advantage of not being liable to be moth-eaten, some specimens of early date have been left us.

It would take us much too long to discuss the much-disputed question of the actual date of some of these scraps, such as those found in the tomb of Charles the Great at Aix la Chapelle; it is enough for us that, as I have said, they undoubtedly represent the design of the stuffs of Justinian's period, and through that period throw light on the fashions of Old Rome, and even of classical Athens. These earliest Byzantine or quasi-Byzantine stuffs are most commonly figured with contiguous circles or wreaths, which enclose divers subjects—sometimes the chariot race in the hippodrome, the consular sacrifice, the Byzantine emperors as consuls of the Republic being the chief figures; the lion hunt in the Emperor's arena, or the park of the great king; the gladiator again dealing with his lion in the arena, and probably doing duty for Samson in the eyes of the devoted Byzantine Christian. All these subjects take us away into classical times, but there are other subjects within these Byzantine or early Mediæval garlands which carry us further back, and hint at a time before the dawn of history, much simpler though they be on the surface, for often these circles are *inhabited* by beasts winged or otherwise, griffins, elephants, and birds opposing one another, as the heralds call it, on either side of an upright object, sometimes branched variously. Now, though you may think that this is a very natural way of filling a circle ornamentally, yet I think it has been conclusively proved

that these beasts and their dividing object are symbols of ancient worship, the object being perhaps translated by the Zoroastrians as the holy fire, though originally signifying the holy tree which has played such a curious part in ancient symbolism or betokening of mysteries.

So then Constantinople takes us back not only to the time of the Caesars, on one side, but on the other also to that of the great king of Persia, to the kings of Assyria, the monarchs of Babylon, and far beyond them to the Accadian people and their astronomical lore.

But if Constantinople was the capital of the weaver's art till the twelfth century, during the next two centuries Palermo took her place. The chroniclers tell us that just in the middle of the twelfth century Roger, the Norman king of Sicily, in a raid he made on the Eastern empire, took Corinth, Thebes, and Athens, where there was still a considerable silk-weaving industry, and that part of the booty which he carried off from those towns consisted of the silk-weavers themselves and their families, whom he took back with him to Palermo, and established in a royal factory attached to his palace, bidding them teach their mystery to his own people. From that time till past the Mediæval period Sicily was the great workshop for silk goods.

Although this story has been much accepted, told as it was gravely and circumstantially, it must be looked upon as a legend founded on the undoubted fact that in the thirteenth and fourteenth centuries Sicily was the headquarters of the silk-weaving craft. The population of Sicily consisted largely of Saracen tribes, who kept amongst them the skill in the industrial arts which they had acquired in the early Middle Ages; besides, Sicily had been a most important outwork of the Byzantine empire in its palmy days, was in fact much more important than the towns of Greece proper, and was not at all likely to have lacked its due weaving craft. Altogether it seems extremely unlikely that Roger should have been the first of the Norman kings to set up a royal weaving-shed, especially as the Norman kings from the first had affected to imitate Oriental customs, reigning, as I have said, among a population which was really Oriental; and this custom of a royal factory, connected as it was with the establishment of the Seraglio, which it is said the Norman kings were not slow to adopt, would have seemed a necessity to a monarch at Palermo long before the time of Roger's raid on Greece. You may note at this place that these weaving-sheds of Oriental potentates turned out those rich stuffs which were specially used for presents and robes of honour, and that Arab writing intermingled with the design; a fact which has served to date some of these webs beyond dispute, as the writing sometimes includes the name of the reigning prince. A word or two as to these written stuffs will have to be said presently.

Anyhow, however the manufacture was established, there is no question that in the fourteenth century Palermo was headquarters of the silk-weaving craft, and most happily we have abundance of evidence of the kind of work produced there, for a great many fragments have been preserved to us in the treasure-houses of the churches of that and the succeeding century; nay, even in England in spite of the Reformation, some evidence is left us of the long way that these beautiful goods travelled, for on the backgrounds of painted panels in the richly-adorned screens of our East Anglian churches, and on the robes of the saints depicted thereon, are figured patterns more or less accurately taken from these Sicilian webs, which doubtless formed part of the vestments of the sacristy.

North Germany, where the Reformation went on in its earlier days more peaceably and with less destruction than in England, has, however, been the great storehouse of these invaluable treasures, the sacristy of the church of St. Mary at Danzig being particularly rich in them; the museums at Vienna, the Louvre, and our own here are well stocked with examples, which I must say as to ourselves are not treated with the respect (by the public, I mean) which they deserve. For I must tell you that these stuffs, designed at the heyday of Mediæval art, uniting the wild fancy and luxurious intricacy of the East with the straightforward story-telling imagination and clear definite drawing of Mediæval Europe, are the very crown of design as applied to weaving.

To a certain extent they preserved the older fashions, and repeated, though not servilely, the patterns of the Byzantine epoch; the writing on the webs seems to have been used by them as a sort of trade mark, implying that they were of fine Oriental manufacture, only for the most part it is mere sham writing, a scrawl which has borrowed certain obvious forms from the real Arabic letters, whose graceful and energetic curves fitted them specially for this kind of written ornament. For the rest, the resource and the ingenuity of structure, the richness of imagination in these stuffs is amazing: beasts, birds, and compound monsters are frequent, often arranged in opposition on each side of the holy tree or holy fire aforesaid, but often simply passing their lives in the scenes of nature, and generally admirably drawn as to their characteristics, though of course generalised to suit the somewhat intractable material. Then we have castles, fountains, islands, ships, ship-sails, and other such inanimate objects. Finally, the weaver uses the human form often enough, though seldom complete. Half-women lean down from palm-trees, emerge from shell-like forms amongst the woods with nets in their hands,

spread their floating hair over the whole pattern, water their hounds at the woodland fountains, and so forth; now and again definite winged angels are introduced. In one whole class of designs a prominent feature is the sun-dog, as it used to be called in the older English tongue; a cloud barely hiding the sun, which sends its straight rays across the design with admirable effect.

And all these things are drawn at once with the utmost delicacy, and complete firmness. There is no attempt to involve or obscure anything, yet the beauty of the drawing and the ingenuity of the pattern combined give us that satisfying sense of ease and mystery which does not force us to keep following for ever the repetition of the pattern—in short, in most of the designs of this place and period there is nothing to desire either for beauty, fitness, or imagination.

From Palermo the art of silk-weaving found its way into the more northern parts of Italy, and settled definitely at Lucca, the centre of a great silk-growing district, whose manufacture overlaps that of Palermo in date, so that it is not easy to state with any certainty whether such and such a piece of goods was woven at one city or the other; but as the years passed a kind of design peculiarly graceful, but not so strongly accentuated as the earlier patterns, marks this school. These patterns are generally founded on the vine; birds and animals are often introduced into them, but do not play such a prominent part as in the earlier cloths. As to the technique of these webs of Sicily and Lucca, it is on all sides admirable, and in nothing more so than its simplicity; so fertile was the designer, his work so crisp, elegant, and powerful at once, that it would have been the height of bad taste to complicate or huddle it up with tormenting the web into ribs, or stripes, or honeycombs, or herring-bones, or long, weak floats of silk. These are the poor refuges from barrenness of invention which a less artistic age is driven to, and both have used, and still uses, them in a most profuse and wearisome way. One peculiarity I may note about all these early stuffs—gold is freely used in them, but the gold thread is not like that of our time and some centuries back, to wit, a thin ribbon of gilt silver twisted round a floss silk core, but is made by gilding strips of fine vellum, and twisting that round a core of hemp or hand silk. This plan has both its advantages and disadvantages; it does not wear as well as the wire-twisted thread, but also is not so apt to tarnish. The Chinese still use similar gold thread, only substituting gilt paper for gilt vellum does not make so good an article. Before passing to the next century, I must mention that all this while much silk ware was made in the East—at Cairo and thereabout was a manufactory of striped silk, in which the Arabic writing, real and finely designed, played a great part. In this work the gold was always flat strips of the gilt parchment, which marks the special manufactory. In all cases you must remember there was at this time no essential difference between the ornament of east and west; even in architecture the resemblances are more noticeable than the differences; but of course in the lesser art we are considering the needs of climate and manners had not the same influence as in architecture. Accordingly we find not only the same details, but the same patterns in use in Persia and Syria as in Sicily and Italy. It is also interesting to note that pieces of Chinese damask are not seldom to be found as the grounds of ecclesiastical vestments, whose patterns are identical with those even now woven there.

As to Northern Europe, doubtless the ornamental weaving, which was mostly worsted, was chiefly tapestry work; but it seems that some kind of figured stuff other than that was made. In the Edicts of St. Louis mention is made of, first, "tapisserie à la haute lisse," and "tapisserie Saracenois," of which more anon; and also of "tapisseries nostrez," which last are obviously goods made in a long piece for cutting and joining: my own impression is that these "tapisseries nostrez" were work, like the rude flowered stuff traditionally made by the Italian peasants to-day in the Abruzzi for instance, and of which the Roman peasant women's aprons are made; this impression is chiefly founded on the fact that exactly the same make of cloth is woven in Iceland for coverlets, saddle-cloths and the like. It seems, however, that early in the fourteenth century there was some sort of silk-weaving and even velvets in Paris, but I imagine it to have been either plain weaving or tapestry, and the velvet to have been made like a carpet. When the unlucky Frenchmen who were taken at the rout of Nicopolis, 1396, were arranging their ransom with Amorath, and were trying to find out with what rarities they would be likely to soften the heart of their conqueror, they were told that he had a turn for the fine tapestry of Arras, if so be they were of good, ancient stories; fine linen of Rheims would not come amiss to him either, or fine scarlets (more of those afterwards), for, said their friends, as to cloths of silk and gold the king and the lords there in Turkey had of them enough and to spare.

(To be continued.)

A Statue of the late Mr. A. B. Stewart has been erected on the esplanade at Rothesay. It is of bronze, and is 8½ feet high, standing on a pedestal of grey granite 10 feet high. Mr. John Mossman, of Glasgow, was the sculptor. The cost was about 1,000*l*. It is the first statue erected in Rothesay.

## BUILDING IN NOTTINGHAM.

THE report which has been presented to the Town Council by the General Works and Highways Committee shows that there is no town in England in which so many buildings had been carried out during the last two years as in Nottingham. During the past twelve months apportionments have been made for 85 streets, necessitating the preparation and service of at least 700 separate apportionments on owners of property. Altogether, upwards of 2,000 notices have been served in connection with private improvement works during the year. A very large area of land has recently been laid out for building purposes, and this has of course involved the construction of a great number of new streets. Building operations in the borough have been carried on at a very rapid rate during the past twelve months, the number of buildings for which plans have been passed in that period being 3,199. This shows a decrease of 151 from the number passed for twelve months ending October 31, 1882. This diminution in number was caused by the temporary slackness of the building trades in the first quarter of the year 1884. The committee believe that the building of houses and other property in this borough during the past five or six years is of such magnitude as to be almost unequalled in any other town. The committee believe that the town may be congratulated on the character of the house property recently built in the borough; although there has been an enormous amount of what is termed "speculative building" carried on, yet with few exceptions the houses which are built are of a character which will, it is believed, compare favourably with other large towns. The following is a return of plans passed for buildings to be erected in the borough during the last six years:—1879, number of buildings, 2,856; 1880, ditto ditto, 2,399; 1881, ditto ditto, to October 31, 2,987; 1882, ditto ditto, 3,350; 1882, ditto ditto, November 1 to March 25, 1883, 1,465; 1883, ditto ditto, March 26 to March 25, 1884, 3,199.

## LEGAL.

### High Court of Justice.

(Before Mr. JUSTICE KAY.)

SNOW *v.* WHITEHEAD.

The plaintiff in this case had let a piece of land to the defendants, subject to a covenant that no house should be built upon the land of a less value than 400*l*. The defendants, it seemed, had begun building in conformity with the covenant, but the local board had objected to the mode of building, on the ground that there was not sufficient air space behind the houses. In order to comply with this objection the defendants amended their plan of building, and submitted one in which two of the houses were thrown together, a communication being made on the ground floor. The houses were two storeys high, and, as thus altered, they had two separate doors opening to the street, and two separate shop windows fronting to the street. They had each of them a separate staircase; one of them, however, had no kitchen, and in the yard behind, which was common to the two houses, there was only one water-closet and ashpit. The local board approved of the altered plans, and the defendants proceeded to build in accordance with them. It was admitted that each of the two houses, if they were to be considered as separate, was of less value than 400*l*., but if the two buildings were to be treated as one house, the total value exceeded 400*l*. The plaintiff contended that the defendants were committing a breach of the covenant by erecting houses on the land of less value than 400*l*. The defendants called among other witnesses in support of their case, and to prove that the two buildings were one house, the surveyor of the local board, who in the course of his examination admitted in effect that the houses would not, in his opinion, constitute one house without some further internal communication. There was also another ground of action for damages under the following circumstances. The defendants had a house adjoining to a house of the plaintiff's. The defendants had fitted their house with drain pipes which did not communicate with any drain. The water flowing down these pipes settled in the cellar of the defendants' house, and thence percolated into the plaintiff's cellar, doing damage to an amount which was not alleged to exceed 5*l*.

Mr. Justice Kay was of opinion that the two houses in the present case were substantially two and not one, and that therefore a breach of the covenant had been committed. Upon the second point His Lordship stated that the question was whether the defendants by not getting rid of the water in their cellar had committed an actionable wrong. The decision of the House of Lords in *Rylands v. Fletcher* was to the effect that a man who brought noxious matter on to his land, which could not naturally be there, was bound to keep it at his own peril. If one man allowed filth on his land to percolate and poison the well of his neighbour, how could it be said that he was keeping in that filth, which, according to the decisions, he was bound to keep in so as not to injure his neighbour? The principle appeared to him to apply to the present case, and he therefore held that the plaintiff had a right of action, and he assessed the damages at 3*l*.

## ENGINEERING WORKS.

**Putney Bridge.**—On Saturday the memorial-stone of the new bridge connecting Putney and Fulham was laid. It is to replace the wooden bridge which was constructed in 1729 by the carpenter to George II., at a cost of 23,075*l.*, from the designs of Cheselden the surgeon. The new bridge is being built of granite, with five arches, and the width of roadway between the parapets will be 50 feet, comprising a carriageway 32 feet wide, and two footways each 9 feet in width. The arches will be flat and segmental, the centre arch being 144 feet in span, with a rise of 19 feet 3 inches, and giving a clear headway of 20 feet above Trinity high-water mark. The arches on either side of it will be of 129 feet span, with a headway of 17 feet above Trinity high-water mark, and the two end arches 112 feet span, with a headway of 13 feet 9 inches in the centre. The width of the river between the abutments is 700 feet, and there will be a clear waterway under the arches of the bridge of 626 feet. The contract for the work was let to Mr. Waddell, for the sum of 240,000*l.*, and the undertaking was commenced in the summer of 1882. The bridge has been designed and is being executed under the direction of Sir Joseph Bazalgette and Mr. Edward Bazalgette, engineers to the Metropolitan Board of Works. On the memorial-stone, which is on the west side of the southern abutment, and bedded at the level of 18 inches above Trinity high-water mark, is the following inscription:—"This stone was laid by their Royal Highnesses the Prince and Princess of Wales, 12th July, 1884."

## CHURCH BUILDING AND RESTORATION.

**Brawdy Church, Pembrokeshire**, which, for a country parish, is one of the largest in the county and lies off the high road between Haverfordwest and St. David's, was reopened on the 10th inst. by the Dean of St. David's, after the first instalment of the restoration had been effected by Mr. E. Giles, of Carmarthen, under the supervision of the architect, Mr. E. H. Lingen Barker, of Hereford. The work consists of new windows, gable crosses, trenches round building, drainage and ventilation, open pitch pine seats and stalls on wooden platforms, encaustic tile floors in chancel and sacrum, with similar bordering to the stone flagging in passages, repairs to roofs and walls, and the provision of a vestry.

**Govan.**—The foundation-stone of the new parish church has been laid. Externally the church will be like the one that has been taken down, the designs of which were modelled after those of Stratford-on-Avon church. Internally the church is to be completely rearranged, and the entire woodwork renovated. There will be accommodation for 900 people. The whole work is being carried out according to plans prepared by Mr. John Honeyman, architect, Glasgow. Messrs. J. & D. Meikle, Ayr, are the principal contractors.

## NEW BUILDINGS.

**Manchester.**—Additions to Henshaw's Blind Asylum, Manchester, have recently been put in hand. The new works comprise gymnasium, workshop, play-room for girls, servants' hall, and various sanitary improvements. The contract price is 3,355*l.*, and the builders are Messrs. Wilson, Toft & Huntley. The architect is Mr. Charles Heathcote, Manchester.

**Birmingham.**—A block of business premises is in course of erection at the corner of Bull Street and Dalston Street, Birmingham, for Mr. Alfred Humpage. The building, which is six storeys in height, consists of a shop with 82 feet frontage to Dalton Street and 18 feet average depth, having a show-room under and show-rooms and workrooms over. The building, which is Renaissance in character, and executed in red brick with moulded and carved enrichments, is being carried out by Mr. W. Robinson, from designs by Mr. Oliver Essex, A.R.I.B.A., of Birmingham, at an estimated cost of nearly 3,000*l.*

## SCHOOL BUILDINGS.

**Swinton.**—A Board School has been opened in the populous mining district of Roman Terrace, Swinton, at a cost of 1,600*l.*, and to accommodate 250 scholars. Mr. H. L. Tacon, of Rotherham, was the architect, and Mr. C. Bowyer, of Swinton, was the builder.

**Gateshead.**—The foundation-stone of the Southern Memorial New Wesleyan Sunday School and Lecture Hall, Gateshead Fell, has been laid. The architect is Mr. J. J. Lish, and Mr. J. L. Miller, Gateshead, is the contractor. The cost of the whole scheme, when the erection of the school-house and lecture-room are completed, will be upwards of 3,800*l.*

**Leeds.**—The memorial-stones of a Wesleyan Sunday School, Roundhay, have been laid. The new premises, which adjoin the present chapel, will comprise on the ground-floor a minister's vestry, three class-rooms, kitchen, lavatory, and other conveniences;

and on the upper floor, which will be reached by a large, wide staircase, a schoolroom 40 feet by 30 feet, with open timbered roof, rising to a height of 21 feet in the centre. It will be well lighted on three sides by large traceried windows, and ventilated by Stevens's ventilators. The buildings, which are of stone, are being erected from the designs of Mr. G. F. Danby, architect, Leeds, by Mr. G. B. Thain, Wetherby.

**Leamington.**—Two Board Schools, one in Shrubland Street and the other in Leicester Street, have been opened. They are both to be used for girls and infants, and altogether will provide school accommodation for 600 children. Each site contains sufficient land for a boys' school, the building of which is deferred for a time, as there is sufficient accommodation for boys in the existing schools. Messrs. Nicholls & Son, of Birmingham, are the architects for the two schools just completed, one of which was built by Mr. John Fell, and the other by Mr. Bailey.

## GENERAL.

**Mr. Gourlay Steell, R.S.A.**, has been commissioned to paint a companion picture to a group of dogs executed by him for the Queen some years ago.

**A Design by Mr. Henry Holtom**, of Dewsbury, has been selected in the competition for the Free Library and Art Gallery at Swansea.

**Sir Joshua Reynolds's picture, "Simplicity,"** until recently in the possession of the Rev. George Hadow, of Tiverton, has been sold by private contract for 3,760*l.* The painting is a portrait of Miss Theophila Gwatkin, the daughter of one of Sir Joshua's nieces, and an ancestress of Mrs. Hadow.

**A Stained Glass Window** has been placed in the Free Church, West Port, Edinburgh, as a memorial of Dr. Chalmers.

**Mr. C. Marriner, A.R.I.B.A.**, died in London on the 16th inst. For several years he was principal assistant in Messrs. Saxon, Snell & Sons' office.

**An Infirmary** is proposed to be erected for the town and neighbourhood of Workington, and a Committee has been appointed to carry out the scheme.

**Professor Karl Rich Lepsius**, the Egyptologist, has died at Berlin. He was born in 1813, and in 1837 he published "Memoirs on the Architecture and Monuments of the Egyptians." In 1842 an archaeological expedition was sent to Egypt under his direction, and on his return a magnificent folio by M. Lepsius was published at the expense of the King of Prussia.

**Messrs. Archibald Smith & Stevens**, of Janus Works, Queen's Road, Battersea, have received the order for the whole of the lifts, six in number, for Hatchett's new hotel, Piccadilly.

**Messrs. Hawes & Co.** of No. 11, Bloomsbury Court, High Holborn, have opened additional show-rooms at 19B New Oxford Street, W.C. where they have a large selection of their plain and glazed encaustic and decorative tiles, with many new designs, and to meet the increased demand, have added marble chimney-pieces, fenders, &c. to their stock in London, and also stoves with tile slays.

**A Fire** occurred last week at the Royal Armoury or Museum, Madrid, containing the well-known collection of arms, armour, &c., used by many of the Kings of Spain, including Charles V. and Philip II., and their famous great captains, and other valuable curiosities. The armoury is the only portion left standing of the old palace of the Castilian monarchs, and forms one side of a large quadrangle in front of the Royal Palace, being exactly opposite the principal entrance.

**The Council of State in Paris** has issued a decree modifying the rules by which uniformity of height in the houses in Paris is secured. The height of a building, as before, is to depend to a great extent upon the breadth of the road way. Thus, in streets less than 7 metres 80 centimetres wide, 12 metres is the maximum elevation; while in streets of 20 metres and more in width, 20 metres are allowed. This measure, however, does not apply to public buildings.

**The Wallace Statue.**—The following report has been given by the assessors who examined the twenty-five models submitted in the competition for the statue which is to be erected in Duthie Park, Aberdeen:—"Sir Noel Paton and Dr. Rowand Anderson, the assessors of Mr. Steill's trustees, being of opinion that, notwithstanding the ability displayed by several of the competitors, there is no one of the models which in its present state they could be justified in recommending to the trustees for adoption, the trustees resolved that they would not be warranted in carrying out any of the designs as submitted; but in respect of the merit exhibited by No. 4 ('Patriot'), No. 6 ('Spes'), and No. 14 ('Fortiter'), agreed to allow their authors, if so disposed, to submit revised models, which the trustees may or may not accept as they see fit, but for which, in case of non-acceptance, they shall allow to each author the premium of fifty guineas, and defer for future consideration what course shall be followed in case none of the revised models shall be accepted."

# SUPPLEMENT

TO THE

# ARCHITECT

## CONTRACTS, COMPETITIONS, AND TENDERS.

LONDON, JULY 19, 1884.

### EDITORIAL NOTICES.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested as much as possible to make their communications brief. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

### TENDERS, ETC.

\* As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, 175 Strand, London, W.C., not later than 3 p.m. on Thursdays.

\* Correspondents, when writing to notify an extension of time, or an alteration of the date of sending in Competitions or Contracts, are requested in their letter of advice to write at the head of the required change—"Contract Supplement to THE ARCHITECT."

### COMPETITIONS OPEN.

RUGELEY.—July 19.—Designs are required for Additions and Alterations at Grammar School. Mr. Robert Landor, Clerk to the Governors, Rugeley.

NORTH SHIELDS.—Aug. 18.—Plans are required for Alterations and Additions to the Workhouse. Mr. Christopher Scott, Guardians' Hall, North Shields.

### CONTRACTS OPEN.

ASHBOY.—July 26.—For Building Schools. Mr. W. Hague, Architect, 62 Dawson Street, Dublin.

BANBURY.—August 5.—For Building Three Shops and Cottage. The Banbury Co-operative Industrial Society.

BELFAST.—July 19.—For Erection of Shops in Smithfield Market. The Borough Surveyor, Town Hall, Belfast.

BERWICK-ON-TWEED.—July 19.—For Building Two Dwelling-houses. Mr. W. Gray, Architect, Berwick.

BIRMINGHAM.—Aug. 28.—For Erection of Kitchen and other Buildings at the Workhouse. Mr. W. H. Ward, Architect, Paradise Street, Birmingham.

BRADFORD.—July 21.—For Building Shop Premises. Mr. George Milnes, 4 Midland Road, Bradford.

BRENTWOOD.—July 19.—For Building Retort-house at Gasworks. Mr. Jabez Church, 17b Great George Street, Westminster.

BRISLEY.—July 21.—For Building Small Farmhouse. Mr. John Dunt, Surveyor, Great Withingham.

BRISTOL.—For Additions to St. Jude's Church. Mr. E. H. Edwards, Architect, 5 Clare Street, Bristol.

BURY.—July 21.—For Building Sheds, Fernhill. Mr. J. Cartwright, Borough Surveyor, Bury.

BWLCHGWYN.—July 21.—For Building Parsonage, Stable, and Boundary Walls. Mr. J. E. Lash, Architect, 1 High Street, Wrexham.

CARLISLE.—For Building Stables, Waggon and Van Sheds. Mr. T. Taylor Scott, Architect, 14 Bank Street, Carlisle.

CUPAR.—July 22.—For Building Cottage, Westpark. Mr. David Milne, Architect, Cupar.

DEPTFORD.—July 22.—For Building Hay Stores at Foreign Cattle Market. Drawings at the Architect's Office, Guildhall.

DISHFORTH.—July 25.—For Additions to Church. Mr. George Mallinson, Architect, Hutton Conyers, Ripon.

DODDINGHURST.—July 21.—For Additions to All Saints' Church. Rev. F. Stewart, Rectory, Doddinghurst, near Brentwood, Essex.

GLOUCESTER.—July 24.—For Additions and Alterations at General Infirmary and Eye Institution. Messrs. Waller, Son & Wood, Architects, 17 College Green, Gloucester.

GREAT YARMOUTH.—July 22.—For Building House. Mr. Sidney Rivett, Architect, Southtown, Great Yarmouth.

GUILDFORD.—For Building Schools at Charlotteville. Mr. W. G. Lower, Architect, High Street, Guildford.

GUILDFORD.—For Erection of School Buildings at Stoughton. Mr. S. Welman, Architect, High Street, Guildford.

HEREFORD.—July 21.—For Erection of Cottage and Building on Corporation Farm, Tupsley. Mr. J. Parker, City Surveyor, Hereford.

HORNSEY.—July 31.—For Additions to Local Board Offices. Mr. T. de Courcy Meade, Surveyor to the Local Board, Southwood Lane, Highgate, N.

HOMERTON.—July 23.—For Finishing Nine Houses Clapton Park. Mr. R. A. James, 38 Finsbury Pavement, E.C.

LEEDS.—July 21.—For Erection of Restaurant Buildings, Mr. C. S. Nelson, Architect, Albert Chambers, Park Row, Leeds.

LIVERPOOL.—July 21.—For Building Station, with Hotel, Shops, and Offices. Mr. H. Shelmerdine, Architect, Exchange Station, Liverpool.

MAIDSTONE.—July 24.—For Additions to Ophthalmic Hospital. Mr. E. W. Stephens, Architect, West Borough Chambers, Maidstone.

NEWBURY.—Aug. 4.—For Building School and Master's House for Governors of St. Bartholomew's Grammar Schools. Mr. J. P. Power, Architect, 67 Basinghall Street, E.C.

NORTHMOLTON.—Aug. 6.—For Repairs and Reseating Church. Mr. E. Ashworth, Architect, Exeter.

OXFORD.—July 21.—For Building Villa Residence. Mr. A. H. Wills, Architect, City Chambers, Exeter.

PETERBOROUGH.—July 19.—For Building Cottages, &c. Mr. H. M. Townsend, Architect, The Precincts, Peterborough.

SHEFFIELD.—July 22.—For Casual Wards and other Buildings at the Workhouse. Mr. James Hall, Architect, Paradise Square, Sheffield.

STAMFORD.—July 19.—For Additions to Tramp Day Ward at Workhouse. Messrs. J. & C. Richardson, Architects, 15 Barn Hill, Stamford.

AWARDED SEVEN PRIZES FOR SUPERIORITY, INCLUDING PARIS GRAND MEDAL, 1878, THE CERTIFICATE OF MERIT OF THE SANITARY INSTITUTION OF GREAT BRITAIN, AND THE AWARD OF MERIT AT THE INTERNATIONAL EXHIBITION, 1881.

TO ARCHITECTS.—THE BRICK of the FUTURE, that shall not get dingy or sooty like other Bricks, but, being of a Semi-Vitreous nature, will maintain a clean and washable surface.

## FACING BRICKS AND BRICK ORNAMENT OF TRUE TERRA-COTTA, AS ALSO ARCHITECTURAL WORK, IN WHITE AND WARM-TINTED BUFF.

Made from the Finest Terra-cotta and Stoneware Clays, of a warm and pleasing appearance, of beautiful and superior quality and finish, non-absorbent, acid, fire, and alkali proof, will resist the most severe frosts, and when tested were found to withstand a pressure of 445 tons to the square foot. They have been used in the most exposed parts on the North and South Coasts, and being true Terra-cotta, are warranted imperishable.

Pattern Sheets and Price Lists of superior Glazed Stoneware Sanitary Pipes, and Fire Clay Goods, Chimney Tops, &c., on application.

Sole Manufacturers:—CANDY & CO., Limited, GREAT WESTERN POTTERIES, NEWTON ABBOT, AND 11 QUEEN VICTORIA STREET, LONDON, E.C. Who are also Sole Makers of the celebrated "Granite Vitriified" Paving Bricks for Yards, Stables, and Footpaths, and "Granite Vitriified" Damp-proof Building Bricks, as used by H.M. Government for dock construction, &c. Samples free to Architects and Engineers.

WEST VALE.—July 28.—For Building Sunday School, Mr. W. H. D. Horsfall, Architect, Albany Chambers, Halifax.

WILLESDEN.—July 21.—For Building Manufacturing Premises and Dwellings. Mr. W. D. Bullis, Surveyor, 21 Finsbury Pavement, E.C.

### GRUNDY'S PATENT WARM-AIR VENTILATING FIRE GRATE.

The novelty, superiority, and advantage of this patent  
consist in the heating surface being greater than any  
other Fire-grate introduced to the public. It is very  
simple in construction, and is made in the form of a Stove,  
the back of which is semicircular in shape, with gills  
behind and smoke-nozzle on top, all cast in one piece.  
The same can be attached to any design of a Register or  
Stove front. It is very suitable for schools, class-rooms,  
waiting-rooms, hospitals, officers, dormitories, and dwelling-  
houses, from the cottage to the mansion. Design and  
specification post free on application.

### TESTIMONIALS.

"9 Victoria Chambers, Westminster, S.W."  
"June 10, 1884."  
"Sir,—I have much pleasure in testifying to the  
efficiency of your patent Warm-Air Fire Grate. It has  
been very successful, and given every satisfaction where I  
have used it."  
"Yours, &c."  
"JAMES WEIR, F.R.I.B.A."  
"To Mr. Grundy."  
"Baptist Chapel, Clapham Common, London. Richard  
Webb, Pastor, 10 Grafton Square."  
"February 15, 1884."  
"DEAR MR. GRUNDY,—I have pleasure in testifying to the  
excellency and efficiency of your patent Fire-Grate. It is  
the most charming invention for heating a large room I  
have ever known. I shall have pleasure in showing it to  
anyone who wish to have their schools or rooms pleasantly  
and efficiently heated."

# The Architect.

## ARCHITECTURAL SPONTANEITY.

PERHAPS—although some of us are now beginning to encourage a little more of patriotic doubt about it—the architecture of London may still require to be excused as much as we can excuse it; but at any rate it has one characteristic which, as its merit improves, becomes more recognisable as a virtue of reality—indeed, an artistic virtue however accidental—namely, its spontaneity. Britons, of course, never can in anything be slaves; but they may take credit for perfect seriousness if they claim for the architectural

*ensemble* of their towns, when compared with certain foreign towns, a sort of freedom from the restraints of discipline, which, whatever faults it may induce, is unquestionably a condition that can be turned to solid advantage. In half a dozen words, one of the chief points of difference between London and Paris consists in the fact that in Paris the buildings are so drilled by authority that no one of them can call its soul its own, whilst in London they are so wholly devoid of such drilling as to be all soul, of such sort as may happen. This contrast, we need scarcely say, has often enough been made, but it may be doubted whether criticism has as yet taken the full benefit of it. What we will venture to lay down, therefore, as an artistic principle, is this: that private indiscipline, that is, individual independence completely asserted, not only may by accident come to be beneficial to the general effect of a town, but must of necessity be so beneficial if individual good taste can be made to take the place of public control. The private building proprietor, in short, if he will consent to subordinate his operations to the control of the artist, may quite safely and quite wisely dispense with the control of the *préfet*; and this it is that produces the quality of individuality or spontaneity of which we are speaking.

In drawing comparisons hitherto between the English towns and the French (more particularly), it is the “monotony” of the French that has been complained of. English people, especially those of a picturesque turn of mind, have allowed themselves to be dreadfully bored by the boulevards. Which ever way they turn, as they have said a thousand times, they see little else than one uniform elevation by the mile; a graceful elevation enough, but so painfully unvaried that its graces are lost in sheer weariness. But this is not the point we desire to make. Spontaneity, if properly estimated, is not a mere negative merit, the absence of monotony; it is a positive virtue, the presence of that essential variety which indicates freedom.

In other words, it is not the monotony, if we may say so, that distresses the English observer, so much as the dragooning of which it is the result. The object in view in the uniformity of Parisian architecture is, of course, not monotony, but discipline; and it would be easy for French dexterity, if such were the order of the authorities, to put this discipline into a form which would not involve anything like monotony. Indeed, we may take leave to express a little wonder in asking why it is that the clever people who administer artistic design in France, publicly and privately alike, have not long ago discovered that the practical outcome of their architectural discipline is scarcely worthy of their artistic resources. No doubt, when the stroller along even the most monotonous of boulevards turns his attention to the diversified design of the gateways and many other such compositions of detail, and regards the general façade, if we may so say, as mere background, he cannot but be charmed with the variety he sees; but he may claim permission to say this is not enough, and he may ask as a very plain question—Why should the general façade be the background, and not the foreground, of the composition?

In London the façade as a whole is so emphatically in the foreground that it constitutes, as a rule, the one subject of design, there being no such special episodes of detail claiming to rivet attention upon themselves. We cannot assert that on this account the artistic merit of the general composition is always so carefully considered as it ought to be; but, such as it is, the best is made of it that the architect can do; and the

result is that each edifice becomes an independent work for what it is worth; and, instead of stately ranges of uniform building, which, as great joint-stock properties, are doubtless sufficiently imposing, we have an undisciplined variety of individual productions, each one claiming its own place and its own importance; and the aggregate effect thus rises to a dignity, if matters are rightly managed, which is entirely different and perhaps superior.

As a typical example of combined façades in London, we need only refer to the terraces of the Regent's Park. In the days of the Regency these compositions, albeit that they are of painted cement instead of stone, were much esteemed, and as a whole, even now, we cannot fairly call them otherwise than elegantly designed. In this case, it is true, as in all others, our inveterate habit of spoiling the skyline has long ago so effectually counteracted the discipline of the original architecture, that even the further outrage of varying the colour of the paint to suit the individual tastes of occupiers scarcely adds to the chaos; but at any rate we need only remark that this is perhaps the best we have to show in the way of uniformity, and that it is not so much to boast of as we could wish.

As a contrast we may refer to the new Northumberland Avenue. Here, it will be remembered, the legislature took a fancy to provide for some sort of artistic discipline. The Metropolitan Board was required by Act of Parliament to refer all designs for building on this new thoroughfare to the Council of the Royal Institute of Architects for approval; and it is safe to suppose that the idea in the Parliamentary mind was something like an expectation that the Avenue would thus become a short but grand “boulevard,” in respect of symmetry if not uniformity. The result, as we now see, is altogether different. What was done *in camera* by the Council of the Institute nobody very clearly knows, because of the singular affectation of imperialism which had taken possession of that little world of art; perhaps it is on this very account that the Metropolitan Board was understood to have declined to accept its advice; but at any rate what we now see in the buildings of Northumberland Avenue is a striking example of true English indiscipline in what we may perhaps consent to call its best form. The edifices are large, costly, and stately, but no adventitious aid to effect is sought for in the adoption of the partnership principle. Each building is a separate composition, and it can scarcely be denied that the appearance of grandeur, instead of being lessened, is much enhanced. Dragooning is notably and positively absent. Independent individualism reigns. Spontaneity is the spirit of the whole. The many works are not in any way one, but in every way many; and if the mere bulkiness of design is not accomplished as it might have been, the value of the aggregate is all the greater, even in the very arithmetical quantity of artistic design presented for the contemplation of the spectator.

With modern Gothic critics the elements of spontaneity would be made to go much farther than this. Their notion of a typical mediæval street is that it was, if not perhaps purposely crooked, beyond all doubt naturally so. The natural line of a bridle-path across the waste is, as all the world knows, a crooked line; and thus it happens that a genuine old street in a genuine old town is almost always more or less out of the straight. This is the general spontaneity, therefore, of the art of laying out streets; and it obviously tells in the same direction as the individual spontaneity by virtue of which the several edifices in the street universally claimed in mediæval times the right to be as unlike each other as they pleased. But none but an enthusiast would approve this characteristic now. And yet, if we compare the disposition of London with that of Paris, in view of this condition as an artistic consideration, may we not, in spite of all our shortcomings, take credit to ourselves for an instinct of spontaneity which has made London capable of becoming a much more charming town, as English art improves in the future, than we may now suppose it possible to be?

Perhaps the case may be put simply thus: that the English instinct of independence shows itself in architecture as in everything else; first, in the acceptance, without reproach, of unconventional lines of streets; secondly, in the recognition of the virtue of individuality in separate buildings; and thirdly, therefore, in the repudiation of the disciplinary elements of regularity and uniformity when they have no other object than superficial order. If this be right, then we have only to add that, within reasonable limits, such spontaneity need never interfere with the qualities of grace, except to facilitate their exercise and augment their effect.

## WESTMINSTER HALL.

WE regret exceedingly that we cannot endorse the proposals of Mr. PEARSON with regard to the future treatment of Westminster Hall, as we can heartily commend his careful examination into and report upon its past. We fear that the antiquarian view of the subject has overborne with him the architectural and artistic, which was not unlikely to happen to so conscientious a custodian of ancient buildings, after the necessarily long and anxious research into all the historical evidences, documentary and actual, of so complex a puzzle as that presented to him.

He tells us that in making his plans for the reconstruction of the west side of the hall it has been his object consistently with present requirements to recover the aspect which it presented in RICHARD II.'s time, and also to retain the existing evidences of earlier and later historical work.

Laudable as doubtless was this endeavour, and suitable as a theme to exercise intellectual students, success in it was both impossible and undesirable—impossible, as is proved by Mr. PEARSON's design itself, which would make RICHARD rub his eyes with astonishment were he, Rip-van-Winkle-like, to revisit the scene of his architectural labours; and undesirable because present circumstances are altogether different, and the requirements of this day various from those of his time.

The difficulties of the archæological problems involved have been most ably and patiently investigated by Mr. PEARSON, and we shall endeavour in a later portion of this paper to explain their entrancing interest, but those of the architectural side of the question are a Gordian knot that needs a different method of solution.

The unveiling of this noble hall of RICHARD II., at the recent removal of the unsightly Law Courts, which had previously almost obliterated it from view, was a revelation; and the effect upon the two grand groups of buildings of the space thus gained—the Abbey, with St. Margaret's, on one side, and of the Houses of Parliament on the other—scarcely less than magical. St. Margaret's Street—or "Lane," as it used to be called, and but a lane it was as a separation between two such mighty piles of building—seemed expanded to due proportions; and from all points of view, particularly as approached from the north, the two splendid groups of structures stood out distinctly and with independent dignity, which was not the case when the buildings of the Law Courts nearly made them continuous. Then the majesty of the proportions of the hall externally, seen for the first time, at any rate, in our generation, asserted themselves, notwithstanding their dilapidation and the squalor of their present surroundings; and their comparative plainness was a relief to the over-ornate character of Sir CHARLES BARRY's portion of the Houses of Parliament with which it has become incorporated.

Mr. PEARSON's design for the reconstruction of the west side of the hall would practically undo all the advantages so gained by the removal of the Law Courts. The flank wall of the hall, with its fine windows, would in perspective, from most points of view, be again obliterated by the double-storeyed cloister he proposes to rebuild between the buttresses; and the building he suggests to advance on the foundations of the old Exchequer Courts, westward from the north-western angle of the hall, would go far to reduce St. Margaret's Street to a lane again, at least in effect. As a wing to the Parliament buildings, and continuation of the quadrangular character of Palace Yard, it is too low in elevation to be in any degree sufficiently dignified, nor is its architectural detail in keeping with them.

It may be, we will concede that it is a fact, that buildings did exist in RICHARD II.'s time upon these very foundations, and that there is actual evidence that the cloister, if cloister it could be called, was of two storeys. The hall was not then a part, and the most prominent part, of such a pile of building as that now existing. We know that kitchens and like offices were needed in its vicinity when its principal purpose was that of a banqueting hall. Such is not now the case, and there is no need for appurtenances of a comparatively mean character to be placed in the front of such a structure as the Houses of Parliament. What appurtenances these were that existed, despite all Mr. PEARSON's ingenuity in unravelling their well nigh inextricable fragments, they were not, judging by the sketches preserved of them, of much architectural character, but were probably considered as mere utilitarian excrescences, done, as everything then was done, with good if not pretentious detail.

Whereas the side of the hall itself, with its well moulded windows, is treated as if it certainly was intended to be seen.

Whether or not this were the case, our contention is that it should be seen now, and the noble buttresses also, as are those of the abbey chapter-house opposite. The cloister-like wall between the buttresses might be carried up one storey without detriment to the hall, but we have no hesitation, after looking at Mr. PEARSON's section of the two-storeyed arrangement, in saying that it can never have been so contemplated by RICHARD II., seeing that the fine arches of the flying buttresses are cut off midway by the roof, leaving the portion above in view and yet incomplete, and the lower portion with its ornamental corbel buried within what is practically but an attic.

When, therefore, Mr. PEARSON proposes "to rebuild the wall between the buttresses in its original position, making an open cloister," we are with him, but as regards "a gallery over it extending nearly the whole length of the hall," we are at issue, seeing that there is no adequate purpose for it, and that it would entirely conceal the fine windows of the hall itself.\* Now that, however, such a cloister will be a principal feature of the building, we should propose that it should be in architectural detail worthy of its position, and not necessarily, as RICHARD may have thought sufficient for his sculleries, "formed of a series of arches which are not only suggested by the wall arches inside, but by the existing jambs found against the large buttresses."†

We have already expressed our deliberate opinion as to the advisability of the proposed building on the site of the old Exchequer Court, and given our reasons for the same. Mr. PEARSON says with regard to this: "On the foundation of HENRY III.'s work I have shown a two-storeyed building projecting westward, of the same height as the cloister, but with a high-pitched roof and gable, towards St. Margaret's Church. This I have designed in character with RICHARD II.'s work, considering the data insufficient to warrant any attempted restoration of the original work of HENRY III. I may mention incidentally that a building with a high-pitched roof existed here formerly in this position." Here would be a puzzle for RICHARD's ghost, who is to see it not as he saw it, but as he would presumably have built it. And yet, in another place we are told that the former building was of three storeys.

When this building existed it was not over-matched by BARRY's structure on the other side of the hall and around Palace Yard, and it is in consideration of these altered circumstances that we think its reconstruction undesirable. Then, again, we might well ask, as doubtless the honourable members will ask, *Cui bono?*

We are told that—

"The lower floor of this is arranged to form a stand for horses, to supply the purpose of a shed at present existing in the same position.

"The upper floor might be one large chamber similar to the old Exchequer Court, and there will be ingress to it by a flight of steps from the hall, and also an approach from New Palace Yard by an octagonal turret at the north-west angle, which will occupy a position not far from one built by Elizabeth.

"The use of this chamber will depend upon those to which the gallery over the cloisters is put.

"As for these uses the gallery can, if desired, be divided into rooms by partitions, there being access by a continuous passage, lighted from the roof. These rooms can be approached by the stairs both at the north and south ends of the hall."

Now the isolated position of this room, with or without the gallery attached, will, we think, render it difficult to invent a use for it, and we cannot but think that RICHARD's ghost would be less puzzled, and the hall preferable, without the staircases above suggested, or doorway, with the larger entrances proposed

\* Mr. Pearson, it is only right to say, alleges that "the height of this cloister wall is accurately marked by the returns of the parapet on the buttresses." In our opinion, however, this makes it so much the worse for the buttresses. We agree fully with Mr. Pearson that "the reconstruction of some of the great buttresses of Richard II. is justified on the strongest grounds—those of stability." We only wish that when they have been rebuilt we should be able to see them, arches and all.

† Mr. Pearson has shown three alternative treatments for the cloisters, and says of the third, of a cloister wall of but one storey, "I can conceive of no advantage from this treatment; there is no gain in accommodation, and the elevation is much impaired" (we venture to think the perspective would not be so). "To carry it out would be to discard the distinct evidence which remains of two storeys having formerly existed."

to be made through RUFUS's walls into the cloister, which is only to serve as a covered carriage stand.\*

Mr. PEARSON says he has shown the completion of Sir CHARLES BARRY's work on the north side of St. Stephen's Porch, in such a manner as he believes he himself would have desired to have seen it completed under present circumstances. This is of course right in every way, but for ourselves we should prefer that it should please Mr. PEARSON living, rather than Sir CHARLES BARRY deceased, and we think that if he had cared less for the ghosts of RUFUS and RICHARD II., and more for the artistic harmonising of the Houses of Parliament of to-day, in the work to be erected on old foundations or otherwise, the result would have been better. The fact is archæology is very well in its way, but architecture and art have their claims as well, and these are the stronger so soon as the ancient work has once perished, and the archæological revival must be more or less a matter of conjecture. It is not possible to serve two masters, and it is by the attempt to do so that Mr. PEARSON has, we think, failed in this instance. The Society for the Protection of Ancient Buildings and scraps, the fear of which he seems to have had before his eyes, admit of no compromise. To please its members he must have the buttresses stone and brick as they are, and prop them up if need be with posts, and perhaps place RUFUS's walling under a glass case. But if buildings be needed for architectural effect let them be the best the nineteenth century can produce, not archæological dreams elicited out of a chaos of fragments of divers dates and wholly different uses from those of the present day.

(To be continued.)

### OLD HALLS IN LANCASHIRE AND CHESHIRE.†

IF there be a part of England which may be said to belong to this age of ours, it surely is the counties of Lancashire and Cheshire. Nowhere else are more acres devoted to the big mills which the nineteenth century can claim as its own, and to the big houses which are needed for the display of the riches of the men whom the mills make wealthy. Tall chimneys, dismal skies, a stunted population, and the other marks of a developed civilisation are to be found there in plenty. But as in English institutions a medley of antiquity and newness, of feudalism and individual independence, often is met with, to the bewilderment of foreigners, so the two Palatine counties can show many of the old halls in which English gentlemen dwelt in days when the cotton trade was as little known as the Declaration of Rights. In the very midst of Manchester itself one can still see a house dating from A.D. 1425, and which is as quiet as a monastery, while here and there in Lancashire there are houses which were planned in days when attacks by Welsh and Northern marauders were among the contingencies for which provision had to be made by prudent builders. Water is an element which is unimpressible to archæological considerations, otherwise it would be seen that many a stream which nowadays gives trouble to sanitary inspectors was at one time regarded as a natural moat, and accordingly turned to account, and we may even recognise the principle of co-operation in the remains of the "folds" which small farmers erected as a sort of joint-stock fortification against outlaws. In a word, although the so-called Palatinate may now care little for the past, unless as a measure to show how greatly it has progressed, yet relics have survived, and too much attention can hardly be given to them. Some, unhappily, are doomed already.

Examples of the "Old Halls" which are the chief of those relics have been illustrated in the lithographs of NASH, and in the volumes on Domestic Architecture by TURNER and PARKER, and occasionally one is made the subject of a paper among the transactions of archæological societies. But it was reserved for Mr. HENRY TAYLOR to produce drawings and descriptions possessing the technical accuracy which is only to be imparted by the hand of an architect. His book is one of which every Lancashire man may be proud. The buildings are interesting, whether considered simply from an architectural

or an archæological standpoint, and as revealing something of life in a past age they are valuable to any historian whose researches have a wider limit than the Court circle. In the illustrations more has been thought of fidelity than pictorial effect. We may go so far as to say that the sketches, which are based on measurements, are preferable to photographs. The halls cover a large site, and the grouping can be most readily realised by means of bird's-eye views, and for obtaining them a lens is useless. The drawings are by Messrs. BALDWIN, BELLHOUSE, WILSON, and HOOPER, and the care which they have taken merits recognition.

The general notion which is suggested by the phrase a Lancashire hall is a two-storey building, having walls of stone and timber, long unbroken roofs which correspond with the plan, square windows in which length rather than height predominates, one or more projecting bay windows, and square-headed doorways. There is an absence of pretension in the exterior. Occasionally there are arched doors and arches in the chapel windows, but straight lines prevail both within and without. The timbers in the interior are sometimes shaped into curves, but the stuff was hard, the pieces were large and difficult to handle, and the men had no wish to fritter them away. What we see is essentially carpenters' woodwork, which is better fitted to "outwrestle time" than to attract by prettiness. But such screens as those which belonged to Salmesbury and Rufford suggest that in richness of carving a hall could sometimes vie with a church. Compared with the English dwellings which belong to a later age, those Lancashire halls might be said to come under the head of cottage architecture; but on that account they are not to be undervalued. If we knew all that occurred in connection with the introduction of loftier houses, we should probably discover that the change entailed misery to many people. When Sir THOMAS OVERBURY described his model yeoman, praise was given because "when he builds, no poor tenant's cottage hinders his prospect." The words speak volumes, and suggest how much was sacrificed when two-storey houses went out of fashion. In such a case a tenant may have been sent adrift; but there is a passage in HERRICK which is evidence that when a man was carried away with the desire to have a finer house than his neighbours in the country, he was not over particular about the sources from whence the materials were derived. The poet, addressing Sir LEWIS PEMBERTON, says :—

Safe stand thy walls and thee, and so both will,  
Since neither's height was raised by th' ill  
Of others : since no stud, no stone, no piece  
Was rear'd up by the poor man's fleece ;  
No widow's tenement was racked to gild  
Or fret thy ceiling, or to build  
A sweating closet, to anoint the silk-  
Soft skin or bathe in asses' milk ;  
No orphan's pittance, left him, serv'd to set  
The pillars up of lasting jet,  
For which their cries might beat against thine ears,  
Or in the damp jet read their tears.  
No plank from hallowed altar does appeal  
To yond' star-chamber, or does seal  
A curse to thee, or thine.

If we remember that HERRICK was an epicurean in his life, and was willing to sacrifice his reputation as a clergyman for a dinner or a bottle of wine, it will be evident that the abuses of the age must have become unbearable to have moved him to so much sympathy with people who did not keep skilful cooks. But no indignation could be wrung from the most sensitive by such buildings as the Lancashire halls. The materials are manifestly used for the first time ; there are none of the refinements of pillars or gilding which were requisite in one of the Anglo-Italian mansions, and neither stone nor wood shows any marks of having once formed part of a church. The owners have no reason to fear any inquiry which may be made into the origin of the buildings.

There is, in fact, nothing to show that ostentation had anything to do with the houses ; at the time of their erection safety was considered to be of more importance. It is difficult for us to understand that it was necessary to employ some rudiments of military engineering in selecting a site for an English dwelling-house ; but as, according to Mr. TAYLOR, preference seems to have been given to defensibility, there is no other conclusion. The sites on which the halls stand are divided by him into three classes, viz. : (1) Naturally defensive sites ; (2) sites naturally defensive, and improved by art ; (3)

\* This is 17 feet wide between walls and 14 feet clear carriage way, so that carriages could only pass through it in single file.

† "Old Halls in Lancashire and Cheshire, including Notes on the Ancient Domestic Architecture of the Counties Palatine." With numerous illustrations. By Henry Taylor, Architect. Manchester : J. E. Cornish.

sites made defensive by art alone. It is not improbable that, like churches, the halls stand on the sites of earlier buildings, and the choice would therefore be made by more ancient inhabitants. The absence of security, as well as other causes, induced the dwellers to live as much as possible together, and the hall or common room, therefore, becomes the principal feature in the oldest class of buildings. Its size and position will enable us to judge not only of the transformations of some buildings, but of the age of others. By a careful analysis, Mr. TAYLOR finds that there are six types of dwellings. First, the Early Gothic small manor-house, with the hall in the centre; second, the Elizabethan and Jacobean small manor-house, when the plan was of  form, and the great hall "was used more as an entrance hall than for the meals in common of master and servants;" third, a development of the first forming three sides of a quadrangle, owing to the size of the servants' wing and the provision for a chapel and private chambers; fourth, the quadrangular, the living rooms being "ranged within the wandering lines of the Bailey walls following the natural lines of easiest defence," and the gate-house and chapel forming the fourth side; fifth, the -shaped type, which indicates that a wing had been removed owing to "the abandonment of the custom of dining in common, to a diminished revenue, and perhaps to dilapidations;" sixth, the large manor-house which is quadrangular like Speke Hall. The English hall reached its importance as a common room in the fifteenth century, and Mr. TAYLOR notes a resemblance with the Icelandic hall. We find from a general table of dimensions that Rufford Hall, which had an open-timbered roof, was 46 feet 6 inches in length, and Baguley Hall was 28 feet wide. Among the halls having flat ceilings the greatest length appears to have been 54 feet, as at Hoghton Tower, and the width of Speke Hall is 34 feet 6 inches. Mr. TAYLOR gives twelve plans drawn to the same scale which suggest that there was no fixed rule about the positions of the bays, angles, passages, and high tables. In some halls a minstrels' gallery existed; the high table was placed under a canopy, and amidst the plainness there was enough to suggest the affluence of the owners. No wonder the change was regretted when fashion, according to the ballad, insisted on

A new-fashioned hall, built where the old one stood,  
Hung round with new pictures that do the poor no good;  
With a fine marble chimney, wherein burns neither coal nor wood,  
And a new smooth shovel-board whereon no victuals stood.

It must have been no easy operation to heat one of the halls by means of wood fires, and the ingles are therefore sufficiently capacious to contain abundance of material and to give room for seats. Mr. TAYLOR believes that the steeply-pitched and lofty roofs in the earlier halls were constructed to allow the smoke from a central fire or brazier to ascend with the least annoyance to the inmates.

A chapel appears to have formed a part of the principal halls. Mr. TAYLOR says that, without much research, he has been able to collect notes respecting no less than fifty domestic chapels in Lancashire and Cheshire. Many still exist, and some continue to be used as chapels. In other parts of England the chapel is supposed to have been erected from a desire to discharge the duty of attending religious services with the least personal inconvenience. The chapel, says Sir JOHN CULLUM, when writing about his house in Suffolk, was a room of state much affected by the whole manorial lords, who seem to have disdained attending the parish church. In Lancashire and Cheshire the chapels were a necessity, owing to the large size of the parishes and the distance of the parish church. The chapel suggests the hiding-place, without which a priest could hardly officiate in one of the manor-houses. A good deal of ingenuity was requisite in the construction of those dens, and at Moreton Hall, in Cheshire, we are told that the floor resembles a rabbit-warren or thieves' quarter. The following description will suggest the arrangements:—

The two secret apartments or hiding-rooms are in the little wing at the back of the gatehouse at its north-west corner. They are each about nine feet square, and in all probability served one as the sitting-room and the other as the bedroom of the unfortunate priest or other fugitive who had to be concealed from his pursuers. The only access to these two rooms is by a sliding panel in the north wall of the apartment over the kitchen; but some pressure must have been applied to a stout priest to get him through this narrow aperture. Of such neat manufacture is the panelling, that much time might be spent by the pursuer in discovering that any part of it was movable, or that anything like a door existed in it.

In the westernmost of these secret rooms is a black-looking abyss or shaft about four feet by three feet, and down this hole the fugitive is said to have descended to the subterranean passage under the moat. Mr. Myott, the agent of the property, informs me that this underground passage, passing under the moat, has been followed up for some distance, a chimney-sweep having been employed for the purpose. This passage leads in the direction of a mound which stands not many yards from the south-west corner. I have not personally investigated the facts relating to this underground passage, but in the nature of things it is not improbable that such a means of escape did once exist. On the ground-floor a bricked-up doorway suggests that at one time there was a means of escape from the dark shaft into the garden. It is a noticeable fact that there are small doorways in the walls of all the rooms in the eastern wing and in the rooms of the gatehouse, so that a fugitive could escape to the secret apartments from the furthest end of the building.

There should be many traditions of hair-breadth escapes about those places; but the historical romance has gone out of fashion. HARRISON AINSWORTH knew a good deal about the halls, and he imbibed a love of archæology from his friend the late Mr. CROSSLEY; but although he introduced some of the legends into his novels he was far from exhausting them. One day a writer may arise who is competent to discover how rich Lancashire is in old traditions, and then the halls will rise in interest. At present they are not valued as they deserve. If the buildings were found in some Continental State instead of in Lancashire they would be made the subject of many a learned dissertation, and the character of the work which is found in them would be interpreted as evidence of the good qualities of the men for whom the houses were built. To the historian the plainness of one of those halls is as expressive as the picturesqueness which is met with elsewhere. Mr. TAYLOR gives us the halls as they now stand, and whatever may be their fate his book will always have interest for everyone who cares for English work. He has spared no pains to make his pages attractive as well as useful, and in justice it must be allowed that he has succeeded. The "Old Halls" is the most valuable book on architecture that the English press has produced within the year. The information it contains is of that kind which is not easily acquired, unless when a writer has a subject which arouses his enthusiasm; but in this case the learning has nothing of the dry-as-dust character.

## TEXTILE FABRICS.\*

BY WILLIAM MORRIS.

(Concluded from page 45.)

THE fifteenth century brings us to Florence and Venice, where the splendid cloths were wrought which were used profusely in the magnificent stateliness of the later Middle Ages. This is a part of the subject that wants treating clinically, so to say; that is, we should be alongside some of the fine specimens in the best museums in order to make you understand it properly. Nothing can exceed the splendour of some of these Florentine and Venetian webs, whose speciality was a particular kind of rich velvet and gold, often with one pile raised on the top of another; in these cloths the vellum-twisted gold gives place to gold thread as we know it, but gilded so thickly that it is not uncommon to find specimens where the gold is very little if at all tarnished.

Rich and splendid as these cloths are, they have, to a certain extent, lost some of the imaginative interest of the earlier designs; it would not be true to say that they depend on their material for the pleasure they give, because in these great patterns, founded on vegetation of the thistle and artichoke kind, there is a vigour and freedom that is most delightful and captivating; but they are more architectural and less picture-like than the Sicilian stuffs: the strange monsters, the fairy woods and inland shores, the damsel-peopled castles, palm trees and shells, the lions drinking at the woodland fountain, hawk, swan, mallard, and dove, the swallow and her nestlings, and the hot sun breaking through the clouds; all these wonders and many another have given place to skilfully and beautifully-arrayed leaves and tendrils. As we shall see later on picture-weaving had reached its height by this time, and there was something of a division of labour between the two kinds of weaving design; at the same time the design was absolutely pure and suitable to its purpose—no atom of corruption had crept in.

Now, as to the relation of this design to that of the east; they still marched close together until the false taste of the Renaissance began to affect the later Mediæval work. Throughout

\* A paper read at a Conference at the International Health Exhibition.

there is more of distinct elegance in the eastern work, and that more especially in that kind of design which we call *Persian*.

The sixteenth century saw the change in woven work which fell upon all the architectural arts. I have said that weaving is conservative of patterns and methods, and this is very obvious of this great period of change. One may say that the Oriental-Gothic feeling, which was the very well-spring of fine design in this art, lasted side by side with diverse new fashions, some of which were merely the outcome of the general pseudo-classical feeling, and showed in detail rather than general arrangement of the pattern, and some pieces of fantastic ugliness, which indicated only too surely the coming degradation of the weaving art.

By the first years of the seventeenth century that degradation had befallen the art in Europe; in fact it was becoming, or had become, no longer an art but a *trade*, as we very properly nowadays call work, which is really but an accident of the profit market. I need not therefore trace its degradation further, though that degradation was checked to a certain extent by the traditions of the better times, and some good work was done until the great flood of the vileness of the eighteenth century swamped everything, and prepared the way for the inanity of the nineteenth, which, in its turn, let us hope, is doomed to prepare the way for a new life once more, even in this small corner of the result of man's intelligence—the textile arts.

Having thus gone very briefly through the story of mechanical weaving, I must now turn back to take up the other side of weaving, and talk of it as producing something which we must call pictures for want of a better word. I have said that in the early days of Greek civilisation, the more elaborately figured cloth must have been either embroidery or tapestry. Of course in the later classical times when the mechanical arts had attained a great degree of perfection, some of this elaborate work might have been done in the mechanical loom, but, judging from Ovid's description of the contest between Minerva and Arachne, which at least admits the possibility of weaving quite an elaborate picture (for they at least were not embroidering), tapestry work must have been practised in classical times. But we need not dwell very long upon these times of uncertain evidence and guess-work, since we have in later times such abundance of clear material for carrying out our inquiries. It is at least pretty certain, as I have already said, that all the more elaborate figured hangings actually made in the north of Europe before the end of the fourteenth century were woven in the tapestry loom. A piece of such work, North German, or perhaps Scandinavian, of the beginning of the twelfth century, is preserved at the South Kensington Museum, itself a portion of a larger piece at Lyons. The design of this piece is practically an imitation in tapestry of the mechanically woven patterns of the south-east of Europe, its design being of that kind of contiguous circles enclosing monsters of which I spoke before. It is worth while noting that patterns of exactly the same character have been traditionally used in Iceland till within the last hundred years; only by that time they have got to be done by means of worsted embroidery upon linen. Now of course you understand that these tapestry cloths were done always for special decorative purposes—for wall-hangings and curtains, I mean—their thick, heavy, and rigid texture unfitting them for use as garment-cloth to the same degree that it would fit them for use as hangings. As on the one hand the northern craftsmen—who had to work chiefly in wool, by-the-by, as I have remarked—had not learned the special mystery of the mechanical figure-weaver from the east, so also this kind of wall-hanging would be likely in the cold, damp climate of the north to take the place of the wall-pictures which so commonly decorated the walls of important buildings in the south of Europe. This, in fact, took place, and the use of tapestry hangings grew commoner as pictures grew more elaborate. The earlier pictured tapestry hangings partook of the simplicity of the paintings of the time, as one can clearly see by the one or two precious relics of that period which we have left. These simple pictured cloths were no doubt woven all over the North of Europe, but one of the chief places of manufacture in the thirteenth and fourteenth centuries was Paris. I have mentioned the Edicts of the time of St. Louis, which show that the craft of tapestry-weaving—"tapisserie à la haute lisse," as they call it—was an important craft at that time. Later on in the second half of the fourteenth century the tapestry-weavers are frequently mentioned at Arras—which city, as you know, has given its name to the whole art—Tournai, Valenciennes, Lille, and Douai. Flanders, in fact, was taking the place in tapestry-weaving which it filled to the last. In the last years of the fourteenth century there is much mention made of the craft, and the names of two designers are mentioned—John of Bruges and Nicholas Batailles—who were both in the employment of Charles V. of France. There is, fortunately, a piece of tapestry still in existence of this period, a portion of a great hanging made for the cathedral of Angers. It represents scenes from the Apocalypse, arranged in frames, and divided by figures of the prophets twice the size of life. It is a grand and monumental work, severe in style, and decidedly belonging, especially as to its scheme of decoration, to the fourteenth rather than the fifteenth century, though it was not finished till about 1453. Of about the same period are certain cloths made in Germany, on a small

scale, not above 4 feet high or so. These are quaint and playful in subject and design, and have a domestic sort of look about them; in fact, I think they were made at the houses they were intended to decorate. The subjects are chiefly secular; scenes from romances, sports, and pastimes, the occupations of the month, and so forth. They were probably meant for what were called dorsars, *i.e.*, cloths to hang at the backs of the diners' benches in the hall. The South Kensington Museum has some good specimens of these.

From the middle of the fifteenth century the art of tapestry-weaving went on vigorously, and we have many specimens left us of the time at least of the latter half of the century. It may interest you to hear what the subjects of the tapestries were which Sir John Fastolf left behind him at Caistor in Norfolk. You must remember he was a powerful country gentleman of second rank in his county). One of the finest pieces of tapestry left, by the way, you will find under the minstrels' gallery in the great hall at Hampton Court, somewhat in the dark; it is in good preservation, and the colour is very beautiful; the drawing is both refined and vigorous, much resembling in style the piece preserved at Berne, which is said to have been designed by Roger van der Weyden. Of about the same period (say 1460) is a piece at the South Kensington Museum of the three Fates standing on a prostrate lady. This beautiful piece is a representative of a particularly pleasing kind of decoration, where figures are introduced on a background of conventional flowers, the finest specimen of which, to my knowledge, is in one of the smaller rooms at the Hôtel Cluny at Paris, but unluckily the guardians of that fine museum have nearly hidden it with heavy pieces of furniture. I think we must consider this kind of work as belonging in spirit to the fourteenth century, though it lasted right into the sixteenth.

Well, tapestry went on getting more and more elaborate, and reached its turning-point about the first years of the sixteenth century, of which period the South Kensington Museum has now, I am happy to say, some very noble specimens—equal, in fact, to any of the time. The tapestry of this period, however, though so much more like a picture than that of the earlier period as to be crowded with figures, and to deal freely with all explanatory accessories—houses, chariots, landscape, and so on—nevertheless is carefully designed on the principles proper to the art. The figures are arranged in planes close up to one another, and the cloth is pretty much filled with them, a manner which gives a peculiar richness to the designs of this period, the opposing fault to this being the arrangement of figures and landscape, as in a picture proper, with foreground, middle-distance, and distance, which plan of arrangement in a woven hanging in which the peculiar qualities of a picture must be lacking, gives a poor unfilled-up look, and at a far greater expense of labour and ingenuity than went to the production of the more conventional arrangement.

We have now come to the end of the Gothic period of this noble art of picture-weaving. The middle of the sixteenth century saw the above-mentioned change take place, and thenceforward the faults which accompanied the degradation of all the arts from that time onward had their influence on tapestry, which, however, died hard so to say. Up to the first quarter of the seventeenth century, tapestries were still made, which though they had lost all the romance and direct beauty of the Gothic period, had some claims to be considered decorative objects: the following period saw the execution of works (at an enormous expense) which were a very bad substitute for the yellow wash of a stable. Up to this time the execution at least of these pictured cloths had been pure and reasonable, had not attempted in any way to imitate the execution of the brush; but from the times of the Grand Monarque and the establishment of that hatching nest of stupidity, the Gobelins, all that was changed, and tapestry was now no longer a fine art, but an upholsterer's toy.

We will leave it in that mud of degradation, to have a few words with its congenier carpet-weaving. Now as tapestry was entirely a western art, so is carpet-weaving altogether an Eastern one. 'Tis clearly an art of the prodigies who dwell in tents or tent-like houses; of dusky rooms with no furniture save a few beautiful pots, and a gleaming brass dish or so; of dry countries where mud is a rare treasure reserved for the sides of wells or tanks, and where people kick off their slippers and walk barefoot when they come into a house.

I think it is a doubtful point as to whether carpets proper were made in Europe before the seventeenth century; although some learned men think that the "tapisseries Saracenois" mentioned in the Edicts of Louis IX.'s time were true piled carpet-work, and it must be said that their reasoning seems rather convincing. Anyhow, there is no direct evidence of carpet making in Mediæval Europe, where, as a matter of course, foot-carpets would be little used in the rough and very out-a-door life then led. But from the middle of the fifteenth century there is abundant evidence of the importation of Eastern carpets into Europe, the most direct and satisfactory of which is given us by the pictures of the period, in which such goods are often shown. These show us carpets doubtless made in Asia Minor, of geometrical designs always, the prototypes of which were obviously floor-mosaics; both the Flemish painters and the Italian paint these things with much accuracy and

enjoyment. But besides these carpets there was undoubtedly another kind of design being carried out at the time, whose headquarters was Ispahan, in Persia. This kind of design was elaborate, flowing, and founded on floral forms, very commonly mingled with animals, and sometimes with human figures. In short the geometrically designed carpets above mentioned have a direct analogy with the earlier Byzantine silk stuffs as to design, and this flowing Persian style with the fewer designs which were woven in the looms of Palermo. Of these latter I do not pretend to fix the dates with any accuracy, but among the specimens I have seen, I will undertake to say that there are representatives of at least three different styles before the degradation of the art—the first being a pure flowing style, following closely in detail the forms of the finest Oriental architectural work, *e.g.*, the plaster ornament at Cairo; the next, affecting much the same detail, but blended with animal form; the third, purely floral, flowing and very fantastic, and ingenious in the construction of its patterns. This last, I think, brings us in date to the time of Shah Abbas, the restorer and upholder of the greatness of the Persian monarchy, about the time of our Queen Elizabeth, and his immediate successors—*i.e.*, from 1550 to 1620 or so. After that the degradation began taking a very different form, as always with Eastern art, than it would have done in Europe, where all degradation of art veils itself in the semblance of an intellectual advance. In the East, on the contrary, haste, clumsiness, rudeness, and the destruction of any intellectual qualities are the signs of degradation—a tendency, in fact, to mere disintegration. As to this special degradation of the carpet-making art, the thing to note about it is that it took as its subject-matter all the different styles I have mentioned—the Byzantine or floor-mosaic style, the flowing fourteenth century, the scroll and beast style, and the floral style. From the *disjecta membra* of these four are knocked up, so to say, the traditional designs which are found in comparatively modern Eastern carpets, which, in spite of all degradation, are still generally very beautiful things, not altogether lacking some sense of logical congruity, and generally good in colour.

It would be an endless task to follow all the ramifications of this art in the East; but I must just say that the Mussulman conquerors of India carried it to that peninsula, where it took root and flourished till quite our own days, chiefly using the more floral side of Persian design, but in some places curiously blending with the forms taken from the native art, Buddhist or Brahminical, and in others infected by the eccentric art of modern China. Modern commercialism, since the days when I was a young man, has laid its poisonous touch upon this useful industry, and to-day it is almost ruined as an art, those importers who have any taste having to exercise great pains and patience in getting fair specimens of it for sale at home.

I have now gone briefly through the tale of woven ornament; but, before I say a few words on what may be called the artistic ethics of this art, I must very hurriedly speak to you of the art of dyeing, since upon that is founded all the ornamental character of textile fabrics. In doing so, I will, for convenience sake, use the present tense, but must ask you to translate it into the past, as this art, most of all among the subsidiary ones, has been turned into a trade, even to this extent—that the public is beginning to be conscious of their loss in this respect, though it is quite helpless to remedy it. Also I must ask you to remember that I am speaking as a dyer, and not a scientific person.

Blue, red, yellow, and brown are the necessary colours from which a dyer makes all his shades, however numerous. All these colours are furnished by natural substances, which have, however, to be modified by the dyer's—or, if you will, chemist's—ingenuity. Of blues there is only one real dye—indigo, to wit. This dye in the ancient classical and the European Mediæval countries was obtained from woad, the Germanic name for an indigoferous plant which can be grown in rich soils as far north at least as Lincolnshire, whereas the true indigo can only be grown in tropical or sub-tropical countries. Indigo, as long as it keeps its colour and nature, is insoluble, and therefore unfit for dyeing. It has therefore to be turned into white indigo by means of deoxidisation, which is effected (I must be brief, and not exhaustive here) chiefly by fermentation. The white indigo is then soluble by alkalies. This deoxidation is called by the dyers "setting the blue vat"; and this setting by means of fermentation—the oldest and best way—is a very ticklish job, and the capacity of doing so indicates the past-master in dyeing.

The next colour in importance is red. Two kinds of substances produce it. First, the powdered root of a plant called in the Germanic tongues madder. Of the madder-producing plants there are several kinds, *e.g.*, clovers or goosegrass, *Galium verum* (our Lady's bed-straw), and woodruff. But they are all poor in the dyeing matter, the true madder having to be carefully cultivated in good soil. Second, there are the insect reds—kermes or coccus, the scarlet of the ancients, which lives, or grows rather, on a prickly oak on the Mediterranean shores; the lac insect, chiefly in India; and cochineal, in Mexico and South America. Of these, madder dyes a dullish blood-red; kermes, a central red tending towards scarlet; lac, a coarse, violent scarlet; and cochineal (used variously), crimson and scarlet.

Next comes yellow, which is vegetable again, and again of two

kinds—one bright yellow, from lemon upwards; the other brown yellow. Weld is the representative of the first; the others are extracted from wood, barks chiefly, and are all more or less astringent.

Now these reds and yellows are dyes of a very different quality from indigo. The textile fibres have little or no affinity for them, and have to be impregnated with mineral substances, for which the dyes have an affinity. These are principally alumina and tin. So used, we call these metals mordants. The widest-spread and most ancient mordant is the alum of commerce. The fibres being steeped or boiled in these mordants, the dyeing forms a lake on the surface of the fibre, and the trick is done.

The browns are, first, vegetable astringents; the extract of walnut root or walnut hulls is the representative of that; and secondly, mineral from the solution of iron, the oxide of which, by-the-by, *i.e.*, yellow ochre, can be formed on fibre, and is especially useful in cotton or linen dyeing.

The other colours are made by mixtures of those above: green, *e.g.*, is first dyed in the blue vat, then mordanted and dyed yellow; purple, blue vat again, mordanted, and dyed red; black, blue vat, mordant red, mordant and yellow, or blue vat and brown. The blue vat has to be continually in use for obtaining all kinds of sub-shades. One famous and historical dye has been extinct for hundreds of years, the ancient purple, the use of which seemed to have died in the earliest Middle Ages. It was extracted from certain shell fish, and was a very permanent and beautiful dye, varying in shade from violet to a fine solid and somewhat sombre red purple.

You must be more careful to distinguish this dye from the other famous ancient one than some of the poets have been. This is the Alkernos or coccus above mentioned, which produces with an ordinary aluminous mordant a central red, true vermilion, and with a good dose of acid a scarlet, which is the scarlet of the Middle Ages, and was used till about the year 1656, when a Dutch chemist discovered the secret of getting a scarlet from cochineal by the use of tin, and so produced a cheaper, brighter, and uglier scarlet, much to the satisfaction of the civilised world, which, by the way, has for the last three hundred years always greeted with enthusiasm every invention which would tend to make its clothes and dwellings uglier and more inconvenient.

I regret that I have but a short space to say a very few words about the last textile which I mentioned to you—dye-painted or printed cloth, to wit—and which I could hardly say anything about till I had given the foregoing short account of dyeing, with which art it is so intimately connected. I have mentioned the fact that Pliny makes it clear to us that this art was known to the ancient Egyptians; but it most probably had its origin in India, a country of all others fittest for following the art on account of its peculiar climate and its wealth of dyeing materials. Whether or not the art was practised in Europe in any form is doubtful, but it does appear at least possible that some of the stained clothes, which we have oftenest supposed to be merely pigment painting in distemper, were dye-painted. In the middle of the sixteenth century the art was firmly established in Persia, whose elegant and beautiful pattern-designing from that time forth has made certain forms of ornament quite familiar to us, in the chintzes that were freely imported into England from the end of the seventeenth century onward; for it goes without saying almost that this Persian ornament conquered everything of cotton printing in India, except the cloths which were made for special purposes figured with the personages and scenes of the Brahmin mythology. It is hardly worth while as an artist going into the history of this art in Europe, since whatever was really fine in it was little more than a literal copy of Indian or Persian originals, of which latter one may say that the peculiarities of the manufacture gave opportunities for special freedom of design and very beautiful colour, founded on the two most important dyeing drugs—madder and indigo.

I did not mean from the first to include the pleasing art of embroidery in this discourse on textiles; so here, if you please, we will end our sketch, and will conclude with very lightly considering the artistic ethics of the subject as I promised. Don't be alarmed, it is but a word or two as to the general quality of the design of textiles in good periods. You will find that whatever merits there may be in textile ornament flows always from an instinct for the fit use of material amongst men of simple and manly lives; which instinct is so strong in pure times of art, that its effects are most obvious to us when the designer, who in those days was also the weaver, was thinking least of his materials when he was wrapped up in the invention and beauty of line of the design he was doing. It was in second-rate times of design, such as in that period of splendid Florentine velvet-weaving I have told you of, that the material was as much thought of as the design, or it may be more so—when in fact the design was used for the display of splendour of material.

In the times of the degradation of the art, with the history of which I have not thought it worth while to trouble you, people gradually forgot that the material had anything to do with the design at all; in fact, they often spent time and pains to make, for instance, woven silk look like printed paper, and so on. Moreover, in the fine time of art, what the designer thought of was always in some way to appeal to the imagination; in other words, to

tell some story, however imperfectly. He had not time, therefore, for the petty ingenuities of the later days; he was determined to let us know what he had in his mind, and he, unconsciously may be, well understood that he was to use fair labour and beautiful form in the simplest and most direct way in order to carry out his purpose. So treated, the design of even a scrap of cloth becomes elevated by human intelligence, and has in its humble way distinct intellectual value; it becomes a thing which no intelligent, unprejudiced man has any right to pass by with contempt as a piece of mere frivolity, and I must say point-blank that unless we can elevate our design into this region of fancy and imagination, we were better to have no ornament at all, for to my mind, as a mere commercial necessity, a bit of trade finish, it is unspeakably contemptible. You may easily imagine that I have not time to give you even any hints as to the way of elevating our ornament on wares; nor perhaps would this be quite the best place in which to treat the subject, which it seems to me, if properly treated, would lead us into very serious matters indeed. One hint, however, I should like to give you. I am myself an ornamentalist, a maker of would-be pretty things. Yet I will not try to press on you the fact that there is nothing like leather; rather, I would say, be cautious of over-ornamenting your houses and your lives with cheap, unenduring prettiness. Have as few things as you can, for you may be sure that simplicity is the foundation of all worthy art; be sure that whatever ornament you have is proper and reasonable for the sort of life you want to lead, and don't be led by the nose by fashion into having things you don't want. In looking forward towards any Utopia of the arts, I do not conceive to myself of there being a very great quantity of art of any kind, certainly not of ornament. Apart from the purely intellectual arts, which even must not swallow up too much of life, I can under our present conditions, looking forward from out of the farrago of rubbish with which we are now surrounded, chiefly see possible negative virtues in the externals of our household goods; can see them never shabby, pretentious, or ungenerous—natural and reasonable always; beautiful also, but more because they are natural and reasonable than because we have set about to make them beautiful. We needn't think that this will be an easy matter to bring about, but when it is brought about I do believe some sort of genuine art and ornament will accompany it—it may be in rather a Spartan way at first. From that time onward we shall have art enough, and shall have become so decent and reasonable that every household will have become a quiet daily unadvertised health exhibition.

## REPORT ON WESTMINSTER HALL.

By J. L. PEARSON, R.A.

(Continued from page 34.)

ON the foundations of Henry III.'s work I have shown a two-storeyed building projecting westward, of the same height as the cloister, but with a high-pitched roof and gable towards St. Margaret's Church. This I have designed to be in character with Richard II.'s work, considering the data insufficient to warrant any attempted restoration of the original work of Henry III. I may mention, incidentally, that a building with a high-pitched roof existed here formerly in this position.

The lower floor of this is arranged to form a stand for horses, to supply the purpose of the shed at present existing in the same position. The upper floor might be one large chamber similar to the old Exchequer Court, and there will be ingress to it by a flight of steps from the hall, and also an approach from New Palace Yard by an octagonal turret at the north-west angle, which will occupy a position not far from one built by Elizabeth. The uses of this chamber will depend upon those to which the gallery over the cloister is put. As for these uses, the gallery can, if desired, be divided into rooms by partitions, there being access by a continuous passage, lighted from the roof. These rooms can be approached by the stairs both at the north and south ends of the hall.

I have shown the completion of Sir Charles Barry's work on the north side of St. Stephen's Porch in such a manner as I believe he himself would have desired to have seen it completed under present circumstances.

Regarding the uses to which the open cloister below could be put, I have shown how it would be possible to carry out the suggestion which has been made to me to utilise it as a stand or shelter for carriages. This arrangement has, however, its disadvantages. There is easy space for two carriages to pass in the cloister, but there is a turn at the south door and an incline to reach New Palace Yard, involving a reduction of the open space on the west side of the hall. But with a suitable alteration of the levels of New Palace Yard in front of the hall, whereby the north elevation would be much improved, I anticipate no difficulty in arranging for the ingress of carriages to this cloister at the north entrance. I have shown how this cloister, if left open, can be protected by an iron grate from the dangers to which public buildings are at present exposed. I have further shown as an

alternative treatment how the arches could be filled with tracery and glazed, so that an additional series of rooms opening from the hall could be obtained similar to those on the upper floor. So far as the elevation is concerned, I consider this the second-best treatment, but considerably inferior to the first. The third suggested alternative consists in the erection of a cloister wall to form a building of but one storey. I can conceive no advantages from this treatment; there is no gain in accommodation, and the elevation is much impaired. To carry it out would be to discard the distinct evidences which remain of two storeys having formerly existed.

I have been able to obtain the exact position of the weatherings of the great buttresses from a comparison of the existing work with a figured drawing by Pugin. Their form is substantially the same as that of the one on the east side, which Sir Charles Barry, with apparently no reason, pulled down. Old drawings agree in showing the hall wall battlemented, and I have, therefore, unhesitatingly adopted this treatment. The dormers in the roof being modern and interfering much with the external and internal effect, I propose to remove.

The earliest record of towers at the north end is in a plan in the Crace Collection at the British Museum, by Norden, date 1593, but there is no sufficient suggestion of their form to gather any clue as to what that originally was, and late drawings show them substantially as at present, but without battlements. In Hollar's print, on the other hand, 1647 battlements are shown. The alteration of these towers, therefore, cannot be based upon any reference to history or past record. But it is almost demanded by the extreme ungainliness of the existing front. This ungainliness is to a large extent due to the contiguity of Sir Charles Barry's buildings, the roof of which overtops the eastern tower, and has to be stopped in a most unfinished manner. It is said that Sir Charles Barry fully recognised this, and proposed in consequence to raise the entire hall floor and roof about 10 feet, and thus give it proper importance. No part of the existing stonework which cases the front is earlier than 1820. The battlements are modern, and the large niches in front are conjectural restorations of what existed before. It is certainly hard to believe also that the present windows are copied from anything of Richard II.'s time. The whole front in fact has an air of spuriousness. I propose, therefore, to alter the windows and raise the towers one stage, which, to preserve a domestic character, will include two floors, and I have endeavoured to re-design this so as to harmonise Sir Charles Barry's elaborate architecture with the severer work of the hall. By thus remodelling them, I hope to render them worthy of their position and importance in the group in which they now play so insignificant and discordant a part.

My approximate estimates for the above works are as follows:—

Cost of the new cloister and its extension westward, including the restoration of the buttresses and the west side of the hall. This will embrace the removal of the already worn and dilapidated casing of the upper part added by Smirke, and the replacing of it by masonry well bonded into the Norman cove, and to accord with the character of Richard II.'s work, 21,500*l*.

Cost of the work on the north side of St. Stephen's Porch, being the completion of Sir Charles Barry's work, 5,000*l*.

Cost of the alteration to, and the raising of the two towers at the north end of the hall, including some work to the gable end, 8,800*l*.

## MUNICIPAL BUILDINGS, PAISLEY.

A MEETING has been held in Paisley for the purpose of memorialising the Town Council to reconsider their decision as to the erection of municipal buildings at the Cross, and to press upon them the advisability, on the ground of economy, of again negotiating with the county authorities with the view of yet acquiring the whole of the County Buildings, and keeping the site at present proposed to be built on as an open space. Resolutions were adopted in favour of the memorial, and it was stated that inasmuch as the County Buildings could be bought for 10,000*l*., it was not economy to expend 30,000*l* or 40,000*l*. for offices to accommodate the town clerk, the chamberlain, and the gas and water officials. A deputation afterwards waited on the Town Council to express the opinion of the inhabitants. The Provost said that he was sorry that a difficulty had arisen at the eleventh hour. The plans were all prepared, and as to give these up now would be a serious responsibility, he might fairly ask them why they had not come to state their objections sooner. He then explained the history of the undertaking, stating that the site and building would cost not more than 40,000*l*., to meet which the Council had 19,000*l*., leaving 21,000*l*. to be provided for. They expected that by rents of shops, offices, and other sources of income, they would be able to pay the interest on borrowed money, and also annually to lay past something to the redemption fund. He then compared the scheme with that proposed by the deputation, and endeavoured to show that the Council scheme was more feasible and cheaper. In conclusion he stated that the Council would give the matter their earnest consideration.

## NOTES AND COMMENTS.

THE Corporation of London have passed a resolution which indicates a new departure in sanitary affairs. It is proposed that in all instances where houses are being erected the Commissioners of Sewers shall place themselves in communication with the building or other owner, and treat with him or them for the construction of a proper ventilating-shaft in the chimney-breasts or party or other walls, for the purpose of ventilating the sewers, carrying the ventilating-shafts well above all adjoining roofs. What is meant by "treat" has, however, not been defined. We suppose that in a great many instances the building-owners would be disposed to meet the views of the Commissioners without any expectation of payment; but there may be cases in which the right to insert a ventilator will have to be paid for. But is it safe in all cases to have shafts from the sewers running up walls?

CAPTAIN GALTON suggests the following novel remedy for defective sanitation, nothing less, in fact, than absence from dinners and parties in a house which has not been certified as perfect:—"If people refused to attend dinners or parties where the rooms are filled with bad air, the architect, the builder, and the occupier would soon find means that in every room the air should be pure and of a comfortable temperature." It is not suggested, however, how "people" are to be satisfied on this point. Is it proposed that an invitation should be accompanied by a certificate from one of the self-appointed authorities on sanitary science guaranteeing that the dining-room and drawing-room are to be kept free from an excess of carbonic acid, and that the air has been washed and dried before its entrance?

THERE are enough English schools in connection with the Education Department to furnish accommodation for no less than 4,670,443 scholars. The loans which the Public Works Commissioners have been empowered to advance on the security of the rates amount to 13,421,513*l*. The Department has, in addition, sanctioned loans amounting to 2,614,888*l*. from the Metropolitan Board of Works and in the open market. Up to Michaelmas 1883 the loans advanced to School Boards were as follows:—The School Board for London, 5,201,409*l*.; School Boards in boroughs in England, 4,171,805*l*.; School Boards in parishes in England, 4,434,685*l*.; School Boards in boroughs in Wales, 194,654*l*.; in parishes, 622,642*l*.

THE Bishop of TRURO has issued an appeal for funds towards building the cathedral at Truro. The choir and part of the transept are finished. Even if the idea of building the nave is abandoned, the committee earnestly desire to complete the transept. Unless, however, 11,000*l*. are provided or guaranteed by August 8, they will be unable to accomplish this object, and will be obliged, instead, to spend a large sum on a temporary erection. The Bishop says that unless the wealthier classes give liberal donations, it will be impossible to complete the building in this generation.

THE National Fête in Paris is always made the occasion of conferring honours on French artists, and in spite of the depressing circumstances attending the fête on the 14th inst., the rule was observed. M. CABANEL has been promoted to the rank of commander in the Legion of Honour, M. ROBERT-FLEURY and M. BENJAMIN CONSTANT are now officers of the Order. The new chevaliers are:—MM. RAPIN, WEERTS, CLAUDE, COLLIN, painters; M. THOBARD, sculptor; M. BOITTE, architect; M. DUMAS, Director of the Art School at Lyons; and M. JOLY DE MONTESSON, of the Administration of Civil Buildings and National Palaces.

THE Scottish ratepayer will no doubt be glad to hear that the Committee of Council on Education have arrived at the conclusion that shortly there will be enough schools in Scotland. The official calculation is that, after making due allowance for sickness and other excuses, there should be school-seats provided for one-sixth of the population, or 635,929 school-places. At present the actual supply falls somewhat short of this number, as the accommodation at the close of the year (allowing 8 square feet of area for each child) was 633,701 places, and in several counties the seats are not equal in

number to one-sixth of the population. This occurs either where that extent of accommodation is not called for, the inhabitants of the upper classes being in excess of the normal one-seventh, or where, as in one or two large towns, the wants of the population have not yet been fully met by the efforts of the School Boards. But when the outstanding building grants have been paid, and several schools now in the course of being erected without such aid are occupied, the authorities estimate that the school supply of Scotland will be virtually complete.

ALTHOUGH England has at present so strong an interest in Egypt, little is done for archæological research. M. MASPERO wants money to continue his exploration of the pyramids of Lisht, which can only be undertaken during those days in July and August when the Nile is at its lowest. All that could be obtained for him in this country was 92*l*., but in a short time 1,000*l*. was subscribed in Paris. This is only one instance of the support given in France to archæology. The French Government in 1881 founded an Egyptian School of Archæology at a cost of 62,000 frs. Each year since they have subscribed 50,000 frs. to its support. They bought MARIETTE'S papers for 79,000 frs., and published his last two works at a cost of 72,000 frs. Yet there would be some excuse if the French were not liberal in aiding modern investigations, for enormous sums have been spent on Egyptian archæology from the time of NAPOLEON'S invasion.

THE Master Plumbers in Brooklyn are aggrieved by the indifference of the wholesale dealers to the identity of interests which should subsist between them and the plumbers. The plumber, it is said, stands toward the manufacturer and dealer in plumbing material in the same light as the retail dealer in any other line of business, and should have his proper measure of protection in the matter of discounts and other trade usages. It does not follow that because the architect and builder may offer facilities for a certain amount of trade, independent, in a certain sense, of the plumber, that the latter is to be ignored. The manufacturer must still bear in mind that he is, to a greater or less extent, dependent upon the plumber for such an indorsement of his goods as will secure for them a preference over other goods of a similar character—an indorsement which should carry considerable weight on whichever side it is given. The facilities for an adverse decision are many. The practice in vogue at the present day among property-owners in America is to place the plumbing regulations of new and old buildings in the hands of some plumber of good judgment and ability. There is nothing easier, under such an arrangement, than to practise the law of retaliation upon the manufacturer who ignores the relations which should exist between him and the craft, or in other words, to employ goods manufactured by houses which deal liberally with the trade. The masters maintain that it is only human nature to retaliate in this manner, and if the manufacturer so treated remains stubborn, it cannot be denied that, while such a condition of affairs continues, the plumber is, in a certain sense, justified in pursuing the proposed course. The manifesto suggests that if people wish to have careful plumbing in their houses it is more than ever necessary to secure proper supervision.

THE report of M. FERDINAND DE LESSEPS on the present condition of the works at the Panama Canal will enable the shareholders to realise the greatness of the undertaking. The number of men employed has been increased every month, and in May 1884 there were over 19,000 men. It is calculated that the excavations amount to 110,000,000 cubic mètres, in addition to 10,000,000 cubic mètres of earthworks in altering the course of the Chagres. Up to the end of April 1884, the total amount of work done is represented by 5,243,302 cubic mètres of earth removed. Until January 1, 1884, however, the real work of cutting the Canal had scarcely fairly begun, and of the total of 5,243,302 cubic mètres of earth removed, nearly half, that is to say, 2,482,768 cubic mètres, have been removed in the first four months of the present year. In the total of 120,000,000 cubic mètres of ground to be excavated, 40,000,000 will be taken away by means of dredging machines. The projector says there can be no doubt of the Canal being open for navigation before the close of 1888.

Proposed Shops & Offices on Leicester

DESIGN FOR THE ELGIN TOWN HALL.

BY MESSRS KNOX & HUTTON, ARCHITECTS.

Gablehurst : Brapksome Park : Bournepouth the residence of Mrs Marsden Smedley J. Marsden Smedley Architect  
Surrey Hill - S.W.

## ILLUSTRATIONS.

DESIGN FOR THE ELGIN TOWN HALL.

THE subject of this illustration is a competitive design submitted by Messrs. KNOX & HUTTON, of Edinburgh. As will be seen from plan, the hall is approached from portico leading into spacious vestibule, having two doors leading immediately to area of hall, and ticket-taker's stall between. A handsome corridor is placed on the left, which answers the purpose of access to reserved seats, also access to platform. The platform and accompaniments are so arranged as to be suitable either for musical or dramatic representations, there being scene-docks, retiring-rooms, mezzanine, organ and organ-gallery. The supper-room is approached from side corridor, and has at upper end an alcove containing service-table, behind which is service-room and scullery, with kitchen over. The doors inside of area of hall and supper-room could be rolled back, thus throwing open the entire area for assemblies. Cloak-rooms, &c., for ladies and gentlemen are provided at near end of corridor, with servants' waiting-room immediately opposite.

The approach to galleries would be by stairs on either side of vestibule, and having at landings suitable lavatory accommodation. The gallery would be continued along either side of hall, but so narrow as to be easily carried without the use of pillars; there would in addition be a large back gallery extending over vestibule and portico. Owing to the site being large, the authors have shown the hall well back off the public thoroughfare, thus giving facility for arriving and departing vehicles with the least interruption to foot-passengers. The style adopted is Italian, freely treated, and the cost, without tower, was estimated at about 7,000*l*.

A SMALL COUNTRY HOUSE.

THIS house was designed for a site commanding a particular view, which accounts to some extent for the large amount of balcony accommodation provided on the front, as well as for other arrangements of plan. The materials proposed are red bricks for the wall-facing, red tiles for the upright tile-hanging, and brown for the roofs, the gables being finished in cream-coloured rough-cast and the woodwork of bays and balconies painted white.

Our illustration is taken from a coloured sketch by the architect, Mr. WALTER MILLARD, of 19 Great George Street, Westminster.

CLAREMONT AND GABLEHURST, BOURNEMOUTH.

THESE houses, lately completed, are situate about a mile from Bournemouth West, in the Branksome Park, amidst a forest of pine trees. From the attic windows are obtained views of the surrounding country and the sea. The tower was so arranged to obtain the splendid views across the Purbeck Hills and the Poole Harbour.

Plans have been approved for the billiard-room and conservatory to Claremont, but have not yet been carried out. The houses are built of local stocks, with red facings, and the roof covered with Brosely tiles. Internally the halls, staircases, and mantels have been specially designed to suit the various positions, and the work has been substantially carried out by Mr. FAGGETTER, the foreman of the works, without the intervention of a contractor, from plans and under the superintendence of Mr. J. NIXON HORSFIELD, architect, Surbiton Hill, S.W.

DESIGN FOR WESLEYAN METHODIST CHURCH, SOUTH CLIFF, SCARBOROUGH.

THE design we publish this week is by Mr. GILBERT S. DOUGHTY, of Nottingham. The plan is cruciform, with nave, transepts, and aisles. A choir-gallery for thirty members is placed over vestry, and school and class-rooms in the rear. It was proposed to carry out the erection in sections, firstly erecting the nave and transepts as the church, with the school-rooms complete. Additional accommodation, which was to be shown, would be provided by placing galleries over schools and in transepts, which when completed would accommodate 700 persons. The spire was intended to be added when funds should permit. The exterior was to be of stone; the facing with "Bradford setts," built in the manner of "sneck" walling, and a Yorkshire dressed stone for quoins; the bands to be of rock-faced blue Handsworth stone. The interior to be

finished in red brick and terra-cotta, with stone dressings. The cost of the first portion to be erected was estimated at 3,500*l*.

DESIGN FOR SHOPS, ETC., AT LEICESTER.

THIS design was submitted in a late competition, and was prepared by Mr. ALEXANDER BLEAKLEY, A.R.I.B.A., of Birkenhead and London.

## ARCHITECTS' CONFERENCE AT THE HEALTH EXHIBITION.

THE proceedings of the Conference held under the auspices of the Royal Institute of British Architects, were resumed in the Conference Hall, at the Health Exhibition, on Friday the 11th inst., Mr. George Godwin in the chair, when a paper was read by Mr. E. C. Robins, F.S.A., on "The Impermeable Construction of Roofs, Walls, and Basement Floors, with a Reference to Ventilation and Warming incidental thereto." Mr. J. D. Seddon followed with a paper on "The Construction of Chimneys." After the reading of the papers Mr. C. Forster Hayward, F.S.A., opened a discussion on the subjects treated of, and observed that the importance of having such parts of dwelling-houses as floors, roofs, and walls constructed so that they might not be open to the influence of atmospheric changes, might seem at first sight self-evident to everyone. But this point, enforced in the paper just read, having special regard to ventilation, was nevertheless one well worthy of discussion, connected as it was necessarily with the second paper, which referred more particularly to another detail of construction, so essential in this country and climate not only to comfort but to the possibilities of ventilation, viz., chimneys. The point of discussion was therefore the effect of permeable or impermeable, porous or impervious, walls, floors, and roofs—first, as impermeable to air, bad or good, including heat and cold; second, to water, *i.e.*, damp and rain. If we would ventilate at all scientifically, in any but the most elementary manner, we must have walls and floors impermeable to atmospheric effects. If sudden changes of heat and cold could to any great extent affect the interior of a building to be ventilated, all special arrangements would be upset, and the introduction of wet and damp through the walls would greatly militate against any artificial means employed to ventilate. Impermeable floors in the basement were best secured by asphalte in some form, either as a layer on concrete with smooth surface, or as a bed for wood block or other such flooring. Floors of a similar or inferior nature might be used, such as cement, &c. Impermeable floors above the basement were obtained by the use of rolled iron joists and concrete, with asphalte or cement covering, or perhaps with a wood surface as before. But this touched on the question of fireproof construction. He would refer to a modification of these impervious floors, such as wood joists fitted in with concrete and pugging, and then a surface of cement or tiles, which he had often used for school passages, where fire-resisting material was sufficient as opposed to fireproof construction. They must give up all contrivances for ventilation through these floors, and omit all calculation as to air getting through them into the room through the floor often charged with dust of carpets, &c.; also all need for air-brick ventilation for the floor itself to keep away dry rot, &c. But the floors would be all the more suitable for laying on air-pipes bedded in the substance of the floor, this being more rigid than the ordinary wood joist floor construction.

Walls were obviously imperfect if built of porous material, whether of brick or stone, or with imperfect joints, or without damp-courses, either vertical or horizontal, either in basement or chimneys, where necessary. Hollow walls were well known as expedients which required careful work and some experience to make effective. Even all the galvanised iron ties twisted and bent upwards, and the patent brick bond, were not enough unless care were taken to prevent lodgment of lumps of mortar, &c., during construction; so that in building hollow walls a space for raking out these below was best left to the last. Then the jambs of windows were difficult to manage, and other points required attention. It was certain that these two walls half-brick thick were better than a 9-inch solid wall to resist the wet, and that an outer stone construction should generally have a lining of brick a slight distance from the mere stone face to secure a wall impermeable to wet. But the best of all as against wet, though not always as against wind and draught, was a vertical external covering of tiles or slate. The former obtained in such districts as Surrey, and the latter in Cornwall and elsewhere.

Roofs might be made impervious as floors, and when so made would obviously be flat or horizontal, not sloping. For ventilation purposes this was not an unmixed advantage; but for access to chimnies, and many purposes, a flat roof was in many ways desirable. The use of substances such as hygienic rock-cement in place of mortar for joints, or as a coating internally of hollow walls, to prevent access of damp and weather was to be commended; but of the substances advertised for coating walls exter-

nally, little advantage might be expected, and less for those often mentioned as being certain specifics against damp, &c., internally.

As to ventilation and warming, we must, in thinking how best to utilise our impermeable constructions, remember that we had to feed the human lungs first, and secondly the fire. When warming was not required only human lungs had to be thought of, but the chimney might be of great use, or at any rate, if it existed, could not be ignored in any system of ventilation. Ingress of air was best secured by such tubes as were well understood as "Tobin's"—a convenient though inaccurate name for them—because they could be regulated in height and size, and by small valves and doors also they could be placed regularly around a room away from an outer wall, being supplied from the other side by tubes laid in the floor. The same arrangement of tubes laid in the floor could be adopted to feed the fire, either in the hearth, or at the cheeks at the side jambs. And of course the air could be brought in the same way to the back of the stove or grate if so prepared to receive it, and there be warmed and distributed. Additional access of air could often be obtained—indeed, sometimes only so—by spaces over the doorheads fitted in with louvres, or by special ventilators made for doors cutting into the mid-rail, and avoiding at least the necessity for opening the doors, and preventing cold draughts to the feet. The one of these systems he had applied to schoolrooms, &c., opening on to a corridor, the other to workrooms of milliners and others. For egress of vitiated air the chimney came into use with talc valve and other ventilators, but specially built flues were best lined with circular or square flue piping, but with regulating valves, which were so seldom used. Either accidental or artificial heat, such as gas burning in the tubes, should be used to keep up the essential draught. If it were congenial to our notions of comfort, those Continental tile stoves with tall flues going right through the rooms to the roof would afford, or might be made to afford, effective egress for vitiated air, being conducted by heat either into some adjoining flue or other ejector. The sum and substance of it all seemed to be a strong recommendation to the householder to procure, and so of course be willing to pay, what was necessary to provide good impermeable walls, floors, and roofs, if he would have a preliminary to good ventilation, or even warmth and comfort without draught.

Mr. RALPH NEVILL, F.S.A., remarked that no mention had been made of wall-papers. Wall-papers, together with plaster, were important as materials which retained warmth and kept out the air. Mr. Robins would find no little difficulty in forcing air through such a wall. [Mr. Robins had shown an experiment by which a lighted candle had been blown out by air blown mechanically through stone and brickwork.] But it must be remembered that the force employed was altogether an exaggerated force—quite a tempest. In allusion to the use of felt for roofing purposes, Mr. Nevill said he had known cases where it had had to be stripped off on account of its unpleasant smell. Mr. Seddon said that a 9-inch by 9-inch chimney was better than a larger size. His own experience was the contrary, though he believed Mr. Seddon's plan would answer if a current of air was introduced below the fire. There was, however, a danger that such inlet would get stopped up. People often did stop up air inlets—Tobin's tubes or whatever else. Cold air descended the sides of a chimney, while the smoke and heated air ascended in the middle; and, consequently, in a 9-by-9 flue there was not sufficient space for the descending and ascending currents.

Mr. W. WHITE, F.S.A., said he thought it was not a question of the size of the flue so much as whether the flue were properly constructed. In speaking of rendering them impermeable, he alluded to the slovenly way bricklayers often did their work. He also spoke of instances of mildew and dry rot arising from the use of felt in roofs.

Mr. SCHMIDT, speaking from his experience at Eastbourne, said he found rooms were kept well ventilated by the introduction of Tobin's tubes in boxes at each corner of the room, and an opening centrally as egress.

Mr. ROWE, of Sydney, said that at the other side of the world, 15,000 miles away, they were troubled by the same difficulties as here, and moreover, they had a greater difficulty about Sydney in obtaining materials that would resist the weather. The discussion, he believed, concerned rather the dwellings of the poorer classes than large buildings, and in his part of the world the climate was not a dry one; bricks alone would not keep out the weather; the common stock bricks were utterly useless, so they employed a good deal of cement in constructing ordinary villas in Sydney and its suburbs. Even that was not always successful, on account of inferior workmanship and its being put on too sparingly. If properly done, and if the amount was mixed in proper proportions, it was found to be weatherproof. Glazed bricks were not used to any great extent on account of their cost. He had tested their sandstone against brickwork as to resistance to wet and moisture, and in every case the result was in favour of the sandstone rather than bricks. Sydney itself was built on sandstone. It was a magnificent building stone. The chief architectural buildings were erected in it, and as it aged a little it acquired a fine tone, and the surface became exceedingly hard and impervious to wet. As to chimnies, in large hospitals he had found it necessary to make them 2 feet, and even 2 feet 6 inches, square.

Colonel PRENDERGAST referred to Dr. H. Acland's remarks on the previous day as to the public believing there was, some 35 years ago, a conspiracy on the part of physicians in Oxford, when they talked of ventilating-pipes for water-closets, &c. But there was a poison just as dangerous as sewer-gas, and more subtle—a poison we knew very little about—and that was vitiated air. Yet the public thought slightly of ventilating their rooms. He said rooms advisedly, for he was convinced that the proper way to treat a house was to ventilate each apartment by itself, and not to attempt to ventilate the house as a whole.

After some remarks from Mr. Waterhouse, and Mr. Bradshaw, of Bolton, the discussion terminated.

Mr. Ewan Christian having taken the chair, Mr. Horace Jones read a paper entitled, "A Suggestion with Regard to the Construction of Doors so as to afford Opportunity of Escape from Fire;" and another on "An Economical Mode of Fireproof Construction, adopted in several instances in Public and Private Buildings," after which a short discussion took place.

Mr. DAWSON, in the course of his remarks, said that the staircase, if constructed with care and skill, might generally be made a secure way of escape in the event of fire.

Mr. H. H. BRIGDEN adverted to the importance of having a proper floor surface, which would not easily take fire from accidental sparks from the fireplace, or the overturning of a lamp. Fireproof floor construction was costly, and the ordinary floor was not fireproof at all. He recommended something between these two, such as blocks of wood or concrete bolted together, which produced an inflammable surface. What seemed to meet the requirements of the case better than other exhibits was the ligno-concrete of Messrs. Clark, Bunnett & Co.

Mr. EWAN CHRISTIAN closed the discussion, and said that by constructing a wall with a hollow cavity, you got the same effect as if you had a wall one hundred years old. Roof construction had received less attention than any other part of a building. People did not know the value of the cavity system. People spoke of the insufficiency of warmth in large buildings such as churches, but the fact was that the fault did not lay in the warming apparatus, but rather in the roof, because people did not attend to making roofs as impervious to air as walls. With a roof properly constructed an attic could be made as comfortable as a drawing-room.

## THE AMSTERDAM EXCHANGE COMPETITION.

A STATEMENT has been published containing details of the competition for the proposed Exchange at Amsterdam. The building is to cost from 125,000*l.* to 166,666*l.* sterling. The competition is open to foreigners as well as Dutchmen. The designs are to be sent into the Burgomaster and Aldermen of Amsterdam within four months, but as the date of the conditions appears to be May 7, 1884, the time would expire in September. A plan showing the situation of the building is to be on a scale of  $\frac{1}{500}$ , and there are to be two ground plans, four façades, a longitudinal section, and three cross sections on a scale of  $\frac{1}{200}$ . The drawings are to be sent in under motto, accompanied by a note written in Dutch, French, English, or German. There is no need of an estimate, as the designs will be judged exclusively on the basis of their more or less appropriate and judicious distribution and artistic character.

The jury will be international, and is to consist of the following eleven members:—Vienna, Professor F. von Schmidt, architect; Berlin, Professor J. C. Raschdorff, architect; Paris, P. Sedille, secretary to the Society of French Architects; Brussels, J. J. van Ysendyck, architect; London, Professor R. Kerr, architect; Amsterdam, L. H. Ebersson, architect to the King of the Netherlands, P. J. H. Cuypers, architect, J. R. de Kruyff, director of the Government School of Industrial Art. Commercial Members—Amsterdam, D. Cordes, president of the Chamber of Commerce; A. L. Wurfbaïn, president of the Stockbrokers' Society; T. Hepner, member of the Corn Exchange Committee.

The members of the jury are to give an undertaking that they have not competed, and are without any share in one of the plans. They are to select ten plans, the authors of which are to be entitled to premiums of 1,000 *fls.* Out of the ten five plans are to be afterwards selected, and the authors are to be invited to take part in a second competition. For two weeks, at least, all the plans are to be publicly exhibited.

The programme for the second competition is to be drawn up by the jury, and approved by the town council. The premiums are to be as follows:—10,000 *fls.*, 6,000 *fls.*, 5,000 *fls.*, 4,000 *fls.*, and 3,000 *fls.*, according to the merits of the plans. In consideration of the premiums the authors are to cede to the municipality their plans and subsidiary data. If the plan which gains first premium is found fit for execution, the author—unless there are cogent reasons to the contrary—is to be charged with the execution of the work, the fees being fixed by the council on the advice of the jury. In that case the premium will be deducted. If the works are entrusted to some other architect the author of the first plan is to receive remuneration in money. Before the final decision of the Town Council the plans of the select competitors are to be publicly exhibited for at least two

weeks, and the report of the jury will be published at the same time.

The Exchange is to contain the following rooms, viz., an exchange hall, rooms for various purposes connected with the corn trade, a room where official quotations of the Stock Exchange are to be made up, an additional post-office, a telegraph-office, a telephone-office, a reading-room, rooms for the use of trade in securities, a room for the directors of the Stockbrokers' Society, a refreshment-room, rooms for the Chamber of Commerce, a hall for public meetings of the Chamber of Commerce, a room for the Exchange Commissioners, a room for the Corn-trade Commissioners, room for doorkeepers, attendants, &c., and, if space allows, rooms for offices, public sales, &c.

### THE CRYSTAL PALACE EXHIBITION.

THE following is an alphabetical list of the awards to English artists which have been made in the art section of the International Exhibition at the Crystal Palace:—

*Oil Paintings.*—A. H. Burr, gold medal; Delance, bronze medal; J. C. Dollman, bronze medal; Alfred East, silver medal; J. Forbes-Robertson, silver medal; W. H. Gadsby, silver medal; H. Hardy, silver medal; James Hallyar, silver medal; Ring Haynes, silver medal; W. C. Horsley, bronze medal; Keeley Hallswelle, silver medal; Edwin Hayes, R.H.A., silver medal; Middleton Jameson, bronze medal; Louise Jopling, bronze medal; E. R. King, bronze medal; Gunning King, bronze medal; Yeend King, bronze medal; C. T. Lander, bronze medal; F. W. Lawson, bronze medal; William Linnell, silver medal; Sir Frederick Leighton, diploma of honour; Stewart Lloyd, silver medal; John Morgan, bronze medal; Clara Montalba, bronze medal; J. Watson Nicol, bronze medal; Arthur Stocks, silver medal; W. D. Sadler, bronze medal; W. Sikert, bronze medal; A. Carlton Smith, bronze medal; Topham, silver medal; W. Cave Thomas, silver medal; A. H. Tourrier, bronze medal; Van Prinsep, A.R.A., silver medal; Ernest Waterlow, silver medal; W. Weekes, bronze medal; R. C. Woodville, gold medal; Pollock Maurice, silver medal.

*Water-colour Drawings.*—Wyke Bayliss, silver medal; John Bromley, bronze medal; J. C. Dollman, bronze medal; Thos. M. Henry, silver medal; Clinton Lin, silver medal; Mortimer L. Menpes, gold medal for collection; Du Maurier, silver medal; Paul J. Naffel, silver medal; Thomas Pyne, silver medal.

*Etchings.*—Fine Art Society (Limited), diploma of recognition; S. Cousins, R.A., diploma of honour; Messrs. Cassell & Co., diploma of recognition; *Graphic* collections, diploma of recognition; Nelson Horatio King, silver medal for photographs.

*Screens, Needlework, Tapestry.*—Royal School of Art Needlework, diploma of honour; Mrs. F. Rowan, silver medal; Miss Shoesmith, bronze medal.

*Sculpture.*—C. B. Birch, A.R.A., gold medal; Aristide Fontana, bronze medal; E. Onslow Ford, bronze medal; J. A. A. Gerritsen, silver medal; E. Ed. Geflowski, silver medal; H. Thornicroft, A.R.A., *hors concours*; George Tinworth, silver medal.

### SOCIAL SCIENCE ASSOCIATION.

THE annual business meeting of members was held at the offices of the Association in Adam Street on Tuesday last. A report from the Council, detailing the action taken by the Association during the twelve months ending June, was presented and ordered to be received and circulated. The report dealt with several subjects of interest in regard to which special action had been taken, and among these may be mentioned the Fine Art Copyright Bill promoted by a committee of the Association; the conveyance of land by the system popularly known as one for the registration of titles as opposed to a registration of deeds; instruction in workshops, the International Health Exhibition, &c.

The following appointments in the Association for the ensuing year, 1884-85, were then made:—President, the Right Hon. G. J. Shaw-Lefevre, M.P.; Presidents of Departments—I. Jurisprudence, Mr. John Westlake, Q.C., LL.D.; II. Education, Mr. Oscar Browning, M.A.; III. Health, Dr. Norman Chevers, C.I.E., F.R.C.S., Eng.; Art, the Right Hon. A. J. B. Beresford-Hope, M.P.; Chairman of the Repression of Crime Section, Mr. J. S. Dugdale, Q.C., Recorder of Birmingham. Sir Richard Temple was appointed President of the Council. Mr. Westlake, Q.C., LL.D., and Mr. Joseph Brown, Q.C., were reappointed as Foreign Secretary and Treasurer; and Mr. Andrew Dunn and Mr. Andrew Edgar, LL.D., were re-elected auditors. The following were appointed hon. secretaries of departments:—I. Jurisprudence, Mr. H. N. Mozley, M.A.; Mr. Meryon White, M.A.; Mr. Herbert A. Safford. II. Education, Mr. Rowland Hamilton. III. Health, Mr. H. H. Collins and Dr. Edward Seaton. IV. Economy and Trade, Rev. S. A. Steinthal and Mr. Edward J. Watherston. V. Art, Mr. Philip H. Rathbone and Mr. Arthur H. Mackmurdo, A.R.I.B.A.

The proceedings terminated with the election of the various standing committees of departments, and hearty votes of thanks to the officers for their services during the past year.

It was reported that the arrangements for the annual Congress, which is to be held at Birmingham from September 17 to 24, were in a very forward state.

### HYDE PARK CORNER.

CONSIDERABLE progress having now been made in the works in connection with the removal of the colossal statue of the Duke of Wellington from Hyde Park Corner to Aldershot, the committee appointed by the Prince of Wales with the sanction of the Queen and of the Government, to consider the best means of decorating the open place near Hyde Park Corner, are now in a position to invite subscriptions with the following objects:—

1. The laying out of the place architecturally with suitable decorations, including candelabra.

2. The completion of the triumphal arch in the manner originally contemplated by the architect, the late Mr. Decimus Burton, with bas-reliefs round the pediment, and by the erection thereon of a quadriga in bronze, carrying a figure of Victory. As is already known, it is proposed to submit this important work to a limited competition.

3. The provision of a suitable pedestal for the existing colossal statue, together with its erection on a suitable site, to be selected by the military authorities at Aldershot.

The Government have entrusted Mr. Boehm, R.A., with the execution of a new statue of the Duke of Wellington, and Parliament has voted the necessary money for this purpose. It is felt, however, that the other objects which the committee have in view are not such as should be defrayed out of Imperial funds. It is estimated that these works will together cost about 50,000*l.* (of which it is approximately calculated that the completion of the arch and the quadriga will cost 30,000*l.*), and this is the sum which it is now desired to raise.

It is believed that this completion of the works at Hyde Park Corner will make a worthy approach to the West End of the capital, and suitably commemorate the fame of the great Duke of Wellington in the immediate vicinity of the house which was given to him by the nation.

Subscriptions for the "Hyde Park Corner Improvement Fund" will be received by Messrs. Drummond, Charing Cross, or by the hon. treasurer, Major-General Dillon, C.B., C.S.I., care of Messrs. Drummond.

It will be optional for subscribers to designate which of the above specified three objects they wish their subscriptions to be devoted to. Failing any such expressed wish, the money will go to the general fund.

### IMPERMEABLE CONSTRUCTION IN REFERENCE TO VENTILATION AND WARMING.\*

By E. C. ROBINS, F.S.A.

THE enclosing walls of every house are an important factor in considering its sanitary condition; so also is the roof covering, which, together with the walls, constitute its power of resistance to the winds and weather of our inclement climate. Until late years, however, the site covered by the walls and roof of any building, has been thought to be sufficiently protected by them, and the existence of such a thing as "ground air" has been ignored in constructing the lowest ground or basement floors of buildings.

Having myself witnessed Dr. Renk's experiments at the Hygienic Institute at Munich, which he has been for years carrying on under the supervision of Dr. Pettenkofer, I am able to speak from ocular demonstration concerning the penetrability by air and water of the materials commonly used in the construction of buildings both public and private.

There are circumstances under which it may be desirable that the air should find its way through walls: for example, wherever no other means are provided for the change of the air in dwellings. Indeed, were it not for the flimsy construction of the houses of the poor, and the passage of the air through the outer walls, and through the crevices about door and window openings and basement floors, the air of the rooms would become perfectly stagnant, and be much more unhealthy than it is. But in the construction of the houses of the future upon sound sanitary principles, it is of course presupposed that nothing comes by chance, that the providence of the designer anticipates and provides for every contingency, and thus puts under the control of the occupier the means of warming, ventilating, and maintaining in healthful condition the house he inhabits. To attain this end, it is obvious that in the first place it must be possible to insure that the basement floor shall be impervious to ground air and moisture.

\* A paper read at the Conference of Architects at the International Health Exhibition.

But what is ground air? It is the superincumbent pressure of the external atmosphere which passes through the earth subjected to its pressure to find its escape in the direction of the least resistance, which direction is commonly that forming the site of a house. The resistance to this external pressure is much reduced by the temperature of the air within the house, which is usually much higher, and consequently much lighter; so that there is every inducement from natural causes for a stream of ground air to be continually passing through the basement, or lowest floor from without, unless steps are taken to construct an impervious flooring, the resistance to the passage of the air through which shall be greater than the pressure.

When the earth is clean and the house is pure there may be no great harm in allowing this process to go on, but for one consideration, viz., the humidity of the air so passing during wet seasons. But in populous places, where the earth is fouled by innumerable accumulations of refuse of all kinds, and where defective drainage has rendered pestiferous the very soil upon which the house stands, and leaky gas-pipes have rendered the external soil black and reeking with gaseous deposits, &c., I say under these circumstances it becomes a matter of enormous moment that the house itself shall not be made the safety-valve for the reception and accumulation of all these abominable impurities in the form of imperceptible "ground air."

#### *Impermeable Basement Floors.*

There are two ways of overcoming this evil. The one is by forming an impervious flooring as before mentioned, and the other is by constructing channels under the floor leading to the kitchen chimney flue. These channels should be of porous materials, and should be six feet apart; and by being carried to the kitchen chimney, the ground air will be drawn off with the heated air and smoke of the chimney, and tend to increase the draught in the flue at one and the same time. This was accidentally discovered by Dr. Renk during his experiments at Munich; for, being unable to account for the difference of ground air pressure in different parts of the basement upon which he was operating, he excavated the floor, and found that one of the air flues from the chemical laboratory passed under the basement floor to the foul air extract shaft, drawing with it the ground air in its immediate vicinity, thus relieving the pressure upon a certain area, and giving the confirmatory exception to the rule he was formulating.

The ordinary materials for paving basement floors are all of a very porous character, and where boarded floors are provided no attempt used to be made to cover the soil at all, till the last amendment of the Act governing these matters required a thin layer of lime concrete to be laid over the earth under the floors generally.

The experiments made on various materials show that hydraulic cement is almost impermeable, and a layer of cement concrete covered with pure cement, or an asphalt surface, or concrete formed of Portland cement mixed with granite or slag chippings, and finished with a smooth surface, will answer the purpose desired. But for the sake of comfort and warmth to the feet, it is often desirable that wood should be the covering. This is equally well secured by the adoption of one or other of the many excellent wood block floorings exhibited in this great International Health Exhibition, to be laid on 6 inches of cement concrete. The blocks need not be more than 2 inches thick, and should not be less than 1½ inch thick and 6 inches long by 3 wide. They should be dovetail grooved at the bottom, burntised before using, and bedded in cement. Powdered cement should be brushed into the interstices after the laying is complete, and the surface well washed with pure water and left clean.

Deal, pine, pitch pine, oak, walnut, teak—most kinds of wood will do, which may be planed or polished, and laid in any variety of pattern, equivalent in beauty to a parquet floor. Where there are no basements it would be better that all the rooms should be thus paved, the difference in the purpose of the rooms being expressed by the character of the design and the quality of the material used. Vitreous porcelain tiles are best for passages, being both impermeable and not slippery on the surface. But excellent tiles of every kind are now available for the purpose, and are most easily kept clean.

#### *Impermeable Wall Construction.*

In the second place, let us consider briefly the case of the enclosing walls of a building. Nothing but the observation of carefully conducted experiments will enable you fully to realise the remarkable porousness of the ordinary building materials used for the external walls of dwelling-houses.

The impermeable qualities of terra-cotta give it a foremost place in the decorative construction desirable in all buildings. Mr. Waterhouse has proved its value as a material for use in the metropolis. The Natural History Museum has the exceptional advantage of being, as it were, cased in terra-cotta. In the erection of buildings of the ordinary porous materials, however, precautions may be taken to achieve a similar result. There are a variety of systems for forming hollow walls, the inner and outer casing being connected with strips of bent iron galvanised. But hollow walls are not always efficient, and are rarely perfectly

well done, and, of course, leave a space into which bad air can accumulate, and vermin may some day find their way and be unable to get out and die, and thus fumigate the building. The system is costly too, and covers a larger area than solid walls.

There is another system which makes a wall at once air and waterproof so far as it extends, leaving nothing but the crevices in the ill-fitting of the joiners' work of doors and windows, which only good workmanship can eliminate. It consists of an asphalt bond between the inner and outer casing, applied in the following manner. Let us suppose a 14½-inch wall, on one side 9 inches of brickwork, on the other 4½ inches, with 1-inch division between, the opposite joints being left free of mortar for about three-quarters of an inch each. At every two or three courses the heated asphalt is poured in, and the crevices all filled up with this impervious material, and the result is a wall much stronger than the ordinary wall, occupying no more space, and perfectly wind and weather-proof. Impermeable water tanks may thus be constructed, an example of which may be seen in the Parkes Museum.

In facing with stonework, this will be found a valuable accessory, but the preservation of the face of the stone will not be secured, and another and a wider question is opened up as to the best kind of preserving solution for treating stone and other porous facing materials, and preserving it from the action of the weather and disintegrating gases afloat in the atmosphere, and found to be so destructive in London, and the manufacturing towns of the provinces. But before discussing this question, let us return to the impervious walling, to observe that there is still a weak point not rendered impregnable to damp air.

#### *Damp Courses.*

The asphalt must not only be applied vertically but also horizontally at the foot of the wall and at the level of the lowest floor adjoining. In fact, the asphalt may be continued at the level of the underside of the wood block basement flooring and so seal up the walls and floor.

This horizontal course in walls is called a damp course, and is usually applied, but when it is absent the result is that damp rises in the walls forced up by the pressure of the ground air by the variations of temperature, by capillary attraction, &c., and the plaster becomes demoralised and falls off the walls, and considerable discomfort and expense is the consequence.

#### *Preserving Solutions.*

This was the subject of an interesting discussion at the Institute many years ago, under the presidency of the late Sir Wm. Tite, and in the transactions of the Institute the whole matter was very carefully reported. I invariably specify that the stonework shall receive when in a dry state, two coats of a solution, the effect of which is to render the surface of the stone comparatively impermeable, at all events, till such a time as the stone has had time to weather and form its own skin and natural protector from, the weather. In fact, wax and gum are dissolved in a spirit, and the solution is applied with a brush on dry stonework: the spirit volatilises, and the congealing of the rest forms a skin as thick as the stone is impregnated; two coats are usually sufficient.

At Hanover Church, Regent Street, may be seen three different processes, none of which have as yet shown signs of failure. The building had become perfectly black, but very few signs of decay had taken place except in the towers, and I was desirous of removing the soot without taking away the weathered surface of the stone, and this I achieved by the use of the wet steam jet. I also discovered that the portions which had been treated with linseed oil when first erected fifty years ago had not decayed to any extent, while the rest was so far gone, that the greater part of the stones had to be replaced.

Of course a great deal of the defective stone we see arises from injudicious selection; there is good and bad stone of every kind, and unless pains are taken not only to select the quarry itself, but to mark the approved stones at the quarry, and then to see that they lie in the building on the same bed that they lay in the quarry, disappointment must ensue whatever the solution you employ; solutions should only be used to preserve good stone, not to make bad stones pass muster.\*

#### *The Roof.*

A very few words must suffice to dispose of this subject, having regard to our limitations as to time. It is not my intention to speak of flat roofs of fireproof construction, and covered with impermeable materials of various kinds; obviously they are rarely required, and, when wanted, only need to be well executed to answer the purpose intended. But the ordinary house-roof is a thing that forms a hat to a building; it may or may not have projecting eaves, or a brim to the hat, but it is always presumed to rise above the greater part of the topmost rooms, and to form an air space protective of the inmates from the extremes of heat and cold. That this is but a presumption is, in many cases, only too true, and the cruelty of putting servants in slate, or even metal-

\* I have had models made of an ordinary brick-wall, and one with asphalt core, both of which I have fitted with caps to show the passage of the air through one and its exclusion in the other.

covered attics, within a few inches of the outer air, is often forgotten alike by the builder who sells, and the master who buys his family residence.

The ordinary speculative house-builder gets the thinnest slates, often absorbent of moisture and permeable by the sun and wind, and he fixes these with common nails to sappy battens, secured to light rafters at the least available gauge, instead of making every third slate lap the first at least three inches, and be fastened with two copper nails to each slate to inch rough boarding, through which the snow may be further prevented from finding its way by putting an intermediate layer of inodorous felt, and thus keep back the heat and the cold and the rain and the snow, and form a sound external covering to the house.

Zinc does not last above a dozen years in the English climate, as a rule; but if used, it should be put on with laps, and without soldered seams or anything to hinder its free expansion or contraction, and should be put in much thicker than is customary—not less say No. 15 gauge.

Lead forms the best and most durable roof covering, properly laid, of sufficient thickness—say 5 lbs. weight for the square foot for ridges and flashings, 7 lbs. for gutters and flats. But nothing is more effective than tiles, and nothing, when well done, warmer in winter or cooler in summer. The Broseley tiles are admirable in colour and hardness.

Projecting eaves are a great protection to the walls; and the projections on the face of the walls for cornices, labels, strings, should all be well under-cut, not only because of the good effect of a sharp shadow, but because the water is thus prevented from running down the face of a building and disfiguring it, and making it damp.

#### Ventilation.

It is not my purpose to enter very deeply into the question of ventilating and warming, but it is obviously necessary to make suitable provision for ventilation not only for the purposes of human respiration, but for the sustenance of the healthful condition of the materials used in the construction of a house. Dry rot, and other forms of premature decay, being induced by the want of a free circulation of air about the places where it appears, the best proof of which is that by the introduction of the air the growth of the fungus is arrested. As I have already remarked, the exclusion of the air from the enclosing roofs, walls, and basement floors of dwellings renders it necessary to provide ventilation of a simple kind, and I shall conclude my paper with a few remarks upon the subject.

If we have something to learn from foreigners of the scientific application of the principles of warming and ventilating great public buildings, as I have elsewhere shown, foreigners have much to learn from us of the domestic comfort derivable from the homely fireside of the English people. That it is wasteful of fuel is true; polluting to the atmosphere cannot be denied. Nevertheless, it is the best system of warming and ventilating ordinary living rooms. But few rooms have any corresponding inlets, and so to supply the omission, whizzing draughts come in through the keyhole and crevices of the doors and windows and floors, and even through the walls themselves. When there is no fire the aspiration by the chimney-flue is much diminished, but might be maintained throughout the summer by the use of a ring of gas-jets just over the mouth of the register. There are circumstances, however, under which this system is inapplicable, and the guidance of a professional man is desirable in all cases.

### THE CONSTRUCTION OF CHIMNEYS.\*

By JOHN P. SEDDON.

CHIMNEYS, at present at any rate, are integral and important features of ordinary buildings in England. It may be that they can and will ultimately be altogether dispensed with, and our towns made, by the progress of economic science, to resemble those in the East—mere collections of flat-roofed boxes; and these may possibly be fed with fresh air of varied temperature, and drained of their fouled air by some parish pump and common heating apparatus. When this scientific millennium arrives such dwellings may be left to purely scientific men, to whom æsthetic considerations are questions of superfluity.

I have, however, now to speak as an architect, addressing a sanitary conference, upon chimneys as existent, and I wish to show how they can and should be treated, that they may be practically useful and ornamental as well. They have been both in former times; witness the graceful chimney-shafts of Grosmont Castle, Southwell Priory, Hampton Court, and a host of Elizabethan mansions, the acknowledged picturesqueness of which is mainly due to the treatment of their chimney-stacks. Alas! however, they are seldom either useful or ornamental nowadays, as a glance at the skylines of our streets will reveal, since they are almost invariably disfigured by ugly cowl and "tallboys." These are but records of domestic misery and discomfort, every one repre-

sented a martyrdom, endured until it became intolerable; and their aggregate cost amounts to a tax upon the inhabitants of our cities which, were it an enforced one, might lead to a revolution. Yet the makers of such monstrosities occupy no inconsiderable space in this very Health Exhibition, and recommend their wares as palliatives for a disease which they assume to be not only universal but inevitable. I maintain that it is not the latter, and need not be the former, and that such costly and ugly excrescences may be altogether dispensed with if but a little attention be given to the proper construction of these portions of our buildings—chimneys and fireplaces.

Now, let me ask, Why do our chimneys smoke? Firstly, because, as a rule, air is not laid on or provided to houses as water is; but rather, indeed, it is in general sedulously excluded. The more sanitariously impervious (that is to say, air-tight) we make our dwellings, the more necessary it is to provide for the admission of fresh air to their interiors, and, unless this be done, smoke cannot ascend the flues of their chimneys; secondly, chimneys smoke because the fireplaces are ill-constructed, and gathered over from the openings of the fireplaces to the flues in such a gradual manner as to leave large vacant spaces above the grates, which act as reservoirs for stagnant cold air, by contact with which the smoke is chilled and prevented from rising and being drawn at once into the flues; thirdly, chimneys smoke because flues are ordinarily made too large (the usual size is 14 inches by 9 inches); they should rarely be made more than 9 inches by 9 inches; fourthly, because no provision is made in the flues for such draughts of air as may invade them to expend and exhaust themselves before they reach the fireplace; and fifthly, because the tops of the chimney-shafts are not carefully constructed with guards against wind in a proper and slightly—that is to say, an architectural manner. Usually all such provision is left to be supplemented by some miserable metal makeshifts, by the chimney-quacks whose fantastic creations Dickens satirised so keenly, and yet, as it would appear even from this exhibition, quite vainly.

As it is useless to expect that chimneys can properly perform their office, of conducting readily into the outer atmosphere the smoke from fireplaces, unless their construction is proper throughout, I shall treat of the fireplace, flue, and chimney-top as a whole, of which the several parts are inseparably connected; and I shall begin at the bottom with the fireplace, as the most important of the three, and the one most commonly in fault in the case of smoking chimneys, although it is generally the last to be noticed or examined with a view to its correction. The grate itself, however, I shall leave for later consideration, though it is by no means of the least importance.

The first thing to be done is to provide a good and sufficient supply of fresh air to the fireplace from the outside of the building. To insure its being good it is well, when possible, to bring this from as high a level as can be arranged, yet not from the top of the chimney-stack, lest smoke from other flues be drawn down thence with the fresh air. It may be drawn from the lower part of the stack, just above the roof, by special air flues brought down the chimney jambs. This, however, is not always possible, and then it must be brought in through the walls or by pipes through the floors. An advantage of bringing the fresh air to the fireplace, rather than to any other part of an apartment, is that even if cold, it does not produce the inconvenient draughts usually complained of. It spreads thence upwards and gradually, before being finally drawn up the chimney by the fire in the fireplace; whereas, if admitted elsewhere, its passage is direct to the fire, and unpleasantly so to those who may intercept its course. When no provision for air is made, it has to force its way in at windows and doors, with the same result, made all the worse because of the low temperature at which it enters. The air, however, brought to this point, may be tempered or warmed by being made to pass around the grate before it is admitted to the apartment, and an essential for both comfort and health is that it should be so tempered; every grate, stove, or heating apparatus should, in fact, be thus made the fountain or source whence fresh air is admitted to apartments.

The next point to be considered is that of the outlet of the smoke from the fireplace to the flue. The flue should be here contracted at once to its normal size, or rather made a little smaller, immediately above the fireplace, in order to promote a quick draught of the smoke into it. The usual construction of this part of chimneys, already adverted to, does not conduce to this end. The opening of the fireplace is gathered gradually, in an arched form, to the flue, leaving an objectionable space for cold air. Now, arch and chimney-bar may be economically dispensed with by forming a mantle block in Portland cement concrete *in situ*, extending the full width of the wall, and 9 inches longer than the opening, and 9 or 12 inches deep, pierced with the smoke flue in the centre, and one for warmed air on either side. These may be circular, and about 8 inches in diameter, and thus, being slightly smaller than the flue over, will insure a quick draught to the smoke flue. The side holes are intended as outlets for the fresh air that has passed round the grates, and thus can be conducted by flues built above the mantle block to gratings for admitting it into the apartment, either in connection with the chimney-piece, or just below the ceiling.

The construction of the smoke flue from above the central hole

\* A paper read at the Conference of Architects at the International Health Exhibition.

in this mantle block is the next point deserving and requiring consideration. As has been said, this is ordinarily made 14 inches by 9 inches, but this is too large, and as such becomes a frequent cause for smoking chimneys. Flues should not generally be made more than 9 inches by 9 inches in brickwork, and are better if lined with fireclay pipes within such, which reduces them to about 8 inches in clear circular diameter. The interior surfaces of the pipes should not be smooth, or else much inconvenience will be caused by frequent small falls of soot, from its being unable to cling to the pipes at all.

Midway between the top of the mantle block and the ceiling line of the apartment, the smoke-flue should have a portion expanded and formed in such a manner as to break the direct line of ascent of the smoke. This is in order to allow down draughts or gusts of air that have invaded the flues from the top to expend themselves, without checking the smoke as it rises from the fireplace. A flat ledge should be provided in this expanded part of the flue, immediately under the smoke-flue above, that air driven down may impinge upon it, and be diverted, and a sideways rotary motion given to it, directing it upwards again, together with the smoke rising from below. Specially formed pipes can be introduced into flues lined with fireclay pipes for this purpose, and more than one of these may be inserted in the course of the flues with advantage.

We now have arrived at the chimney-stack above the roofs, and the principal object in its construction is to maintain throughout its warmth, as it is there of course exposed to cold and damp; and it is well known and observed that those chimneys which are in external walls are, from this cause, far more liable than others to smoke. Pervious brickwork becomes saturated by rain, and the flues consequently reduced in temperature are unable to maintain the requisite upward draught. It is well, therefore, for this reason as well as for additional strength, that the chimney-stacks above the roof should be built in cement instead of common mortar, and of impervious bricks or stone and lined with fireclay pipes.

The tops of the chimney-stacks need careful arrangement, because the exit of the smoke from them is very liable to be disturbed and hindered by gusts of wind, particularly when beneath other high objects in the neighbourhood. There should, therefore, be at the top of every flue an expanded space, within which most down draughts of air will rotate and expend their force without invading the flue below; and there should be louvred openings so arranged as to direct the wind upwards, and so make it to assist, instead of interfering with or retarding, the exit of smoke. This is the object generally and often rightly attempted by the supplementary cowls, at any rate by the best of them, but it may and should be rather executed in proper architectural form, and durable and slightly materials, such as stone, brickwork or terra-cotta, instead of metal. Terra-cotta is perhaps specially suitable, as being very easily manipulated into the somewhat complicated forms required for the purpose.

So much, then, for the construction of these three parts of a chimney—the fireplace, the flue, and the chimney terminal of the stack. Unless all are well and properly executed, no special appliances for particular parts can be of much avail. I have endeavoured to point out the general principles that I think should be attended to in connection with them, and believing that the health and comfort of the community is at present very injuriously affected by their general neglect, I earnestly commend them to the consideration of this Conference.

There is, however, one more part connected with the chimney which is perhaps quite as important as any of the rest with which I have dealt, but what I have to say about it is somewhat more tentative and experimental. This is the grate within the fireplace. Volumes have been written about it, and yet it remains open for discussion and inviting improvement. My contributions to its literature will be short, and yet it will embody the result of much time and thought expended upon it.

Burning coal principally, as we do in England, we have to seek in the consumption of its smoke, or at least of as large a proportion of it as possible, within the grate itself, the solution of the main difficulties we are considering. For the smoke being consumed, smoky chimneys will be cured. The office of the flue will then be to convey away the gaseous products of combustion only, and not soot. This is, I believe, attainable by means of diverting the current of the smoke, after it has issued from the top of the fire, in such a manner as to force it to pass through the body of the fire before it ultimately is allowed to escape up the chimney flue. Perfect combustion is, I think, more to be sought than what is called "slow combustion," and it is a mistake in my opinion to smother a fire in its own ashes, by preventing their dripping through a grating into an ashpit. The cheerful aspect of an English open fire is not likely to be driven out of fashion by even Health Exhibitions; nor if it could be, and the attempt were made, do I think that the public salubrity would be improved by the substitution of any description of close stoves in apartments, notwithstanding the preference they have obtained on the Continent, and to a great extent in America. Nor do I believe that any of the systems that have been proposed for keeping up throughout dwellings an equable temperature, are likely long to curtail the liberty of English subjects to make their several rooms of whatever degree of heat it may please their oc-

cupants. I should certainly therefore not advise the most ardent believer in such a system to expend capital in building houses otherwise than as at present, or to try to dispense with chimneys, the construction of which I have been dealing with.

But there are many grates shown in this exhibition which presume fresh air to be brought to them, and in which means are provided for warming and distributing such air into apartments, and I cannot too highly commend the system, and advise its universal adoption by the public; and I may point out that this can and should be done, more often than it is, in the case of the kitchen chimney, which is almost always in use, and that the air warmed thereby, not being wanted in the kitchen, should be conducted to the general hall of the house, which supplies air to the rooms whenever their doors are opened, though of course there should be means of shutting it off in summer, when it might prove rather a nuisance than otherwise.

Trusting then that soon, if it be not already achieved by any of the grates shown in this exhibition, that most desirable end, the consumption of smoke within the grate itself will be successfully carried out, I conclude these few observations upon the construction of chimneys, waiting discussion thereon from the members of this Conference.

## SUGGESTIONS RESPECTING DOORS AND FIRE-RESISTING CONSTRUCTION.\*

BY HORACE JONES.

A CONSIDERATION of many of the unhappy occurrences during the terrible catastrophe of fire within my own memory has induced me to formulate "A Suggestion with regard to the Construction of Doors so as to afford opportunity of Escape from Fire." I append a list of the more prominent cases in which, by the newspaper accounts, some five thousand lives are alleged to have been lost. Supposing this is somewhat exaggerated, and there is only one-half or even a fifth of that amount, it will still be a horrible and terrible tale to record against the builders and designers of public buildings.

Amongst those to which my attention has been more especially drawn, I may quote the following, viz. :—

1807. October 15. Sadler's Wells Theatre.—Eighteen persons trampled to death from a false alarm of fire.

1845. May 27. Raggett's Hotel, Dover Street, Piccadilly.—Several eminent persons perished.

Exact date unknown, but about thirty years ago, a whole family were burnt or suffocated through not being able to open the front or street door during a fire, not far from the Marble Arch.

1858. December 27. Coburg (now Victoria) Theatre.—Alarm of fire. Sixteen persons killed.

1863. December 8. Santiago (Church of the Campana), capital of Chili, South America.—About 7 P.M. The feast of the Immaculate Conception of the Virgin Mary, and the last day of a series of religious celebrations, in the month of May. The church, when brilliantly illuminated in a dangerous manner, was burnt down, the fire beginning among the combustible ornaments, and above 2,000 persons, principally women, perished, the means of egress being utterly insufficient.

1866. November 5. In Hampstead Road.—Thirteen lives lost.

1878. February 4.—Circus at Calais Fair.—The loss of life was mainly owing to the supplemental door, for escape in case of accidents, *opening inwards*, becoming blocked. Twelve dead and others not expected to recover.

1878. October 11. Colosseum Music Hall, Paradise Street, Liverpool.—Thirty-seven persons dead and several seriously injured. No relief until the police cut away a partition forming a barrier, which divided the stream of people entering towards the different parts of the auditorium.

1881. December 8. Ring Theatre, Vienna, formerly Opéra Comique.—Total destruction of building and loss of life variously estimated at from 500 to 900 persons.

1883. January 10. New Hall House, chief hotel of Milwaukee.—Fire. Ninety lives lost.

1883. January 13. Fire at Berditzcheff, a town of Russian Poland, in the Government of Kieff, in a circus.—The building in a few minutes was a mass of flame, and 1,500 persons perished.

1883. June 14. Victoria Hall, Sunderland.—Death of 183 children. Probably caused by a bolt slipping into a socket in the floor.

I have had copies of the newspaper accounts made, which give in more detail the fearful occurrences. I have alluded especially to the one at Santiago. It would, however, occupy too much time for me to read them through just now, though anyone can do so, as they are on the table for inspection.

Such, then, are the reasons which prompted my "suggestion"—a suggestion applicable to the large doors of churches, theatres, concert-rooms, or other public buildings; also the street or entrance doors of mansions, hotels, boarding-houses, or any other place

\* A paper read at the Conference of Architects at the International Health Exhibition.

where numerous inhabitants are likely to be in occupation; also to the subsidiary doorways of public buildings, which are only to be in use either for egress under special circumstances such as panic or accident or for ordinary egress. The models, let me observe, will show far better my ideas than any description in words, but I may as well describe while you inspect them.

I will first take the wainscot, one which may be assumed to be about one-fourth or one-fifth the full size, or say about 4 feet 6 inches wide, and nearly 8 feet high. It represents an ordinary door to a large house, or a fair-sized hotel, and nothing is indicated on the outside excepting a six-panel door opening inwards, as doors of this description generally do; an alarm of fire occurs, the people on the inside having rushed down to this, their principal mode of exit, and, in their panic and desire to get out, block the door, either with their own bodies or pieces of furniture which they are in hopes of saving (something of this kind no doubt occurred in the large house at the Marble Arch, already alluded to); but if the unfortunate victims crowding and blocking the door with frenzied fear but not unnatural panic, found suddenly that this blocked door, opening inwards upon them, had a means of safety in itself, by simply opening outwards the folding wicket framed within the door, their chances of escape from almost certain destruction would be very much enhanced, and their thankfulness can be better imagined than described. Of course, if the height of the door admitted it, the upper panels would be framed solid, the wicket opening and shutting to and from the transom only.

The painted and grained model shows a somewhat similar door, only instead of a folding wicket it has only a single door, and would be peculiarly applicable to such cases as that headed the "Circus at Calais Fair," where, according to my information, the deaths occurred through a subsidiary door opening inwards becoming blocked by the people from the circus in their panic-struck efforts to seek egress.

I would here observe that the cost of the extra labour in forming doors with these wickets, as shown by the model, would not be very large, a very small percentage upon the cost of an ordinary door being sufficient; the principal expenditure of course would be in the additional hinges and fastening, although the latter could be of any kind, from an "Espagnolette" bolt down to barrel bolts or bars. They would of course open only from the inside, and either by sealing or other methods insure detection where they had been unnecessarily tampered with. I have no doubt, in fastenings, &c., &c., some of the ingenious minds whom I have now the honour of addressing would readily find, if they think this is a suggestion worthy of attention, some improvement. I would also admit that wickets are often applied to large doors or gates; these wickets are, however, very small, very inconvenient, and generally open the same way as the gates.

I will now proceed to call your attention to a form of construction, or rather an application of the different qualities of two of the best known and most universally used materials.

Some years ago I had occasion to visit an engineer's workshop or factory, that had been then quite recently destroyed by fire—indeed, the ruins were still smoking—and these shops consisted principally of two or three rather lofty storeys. A curious circumstance immediately presented itself: the beams or girders were composed generally of three distinct kinds, viz., cast iron, wrought iron, and timber.

I found all the cast-iron girders, of which there were several, on the ground, broken in pieces; the wrought iron laying, or rather hanging, from the upper floors, twisted into various shapes; the wooden joists generally entirely consumed, nothing but some small remnants of charcoal indicated where they had been; but there were two wooden beams, which, for some special reason had been cased on two, and perhaps in some parts on three sides with thin iron plates. These beams alone remained *in situ*; both were well laden, and supported heavy and massive articles. I inferred from this, that the application of the thin plates to the sides of the timber, prevented the combustion of the timber, whether by preventing the atmosphere getting at the fibre of the wood or from any other cause is immaterial as long as the result is the same.

As a proof to myself and the engineer whose premises were burnt, he tried the following experiment, viz., selecting two or three pieces of ordinary timber, about 6 or 8 feet long, and say 6 by 4 inches scantling, and covering half their length with thin iron, bolted through on two sides. He had them placed in the furnace of a steam engine; in a short time the uncovered or unprotected wood, was entirely consumed, the parts protected had the sides charred, of course, but the middle of the scantling, desiccated thoroughly, yet quite sufficiently firm and solid to carry nearly if not quite its original load. Acting on this information, several floors were executed, as follows; for instance, in the Sovereign Life Office, corner of St. James's Street and Piccadilly; the British and Magnetic Telegraph and Submarine Station, at the rear of the Exchange, Threadneedle Street. One floor in each, dividing portions of the building separately occupied; some warehouses also for the storage of valuable goods, &c., &c.

Of course the progress of improvement would naturally adopt some of the many useful and ingenious modes of constructing fireproof floors, such as using rolled iron joists quite covered or embedded in concrete; but there are times when a different mode

of construction may be advisable, and the application of a useful beam of wood rendered fireproof by the thin covering of iron not be neglected. Of course the embedding in concrete of iron will also apply to wooden joists without the protecting iron case, and if so, an economy will be the result. Few fireproof floors can be constructed under 6*l.* or 7*l.* per square. I am, however, informed of one in which the constructors claim they can construct it at 5*l.* 16*s.* 9*d.* per square.

I have inquired of a respectable and well-known surveyor the ordinary cost of ordinary flooring. His letter is as follows:—

"10 South Street, Finsbury, E.C.: July 4, 1884.

"Dear Sir,—We have carefully estimated in detail the cost of the fireproof flooring according to and as shown by your section, and we find that for a room of say 24 feet by 16 feet the cost will be 4*l.* 10*s.* 6*d.* per square, being about 7*s.* per square less than an ordinary floor construction, with fir joists 12 inches apart, 1½-inch yellow deal flooring, two courses of herring bone strutting, and lath and half and plaster ceiling. If instead of the floated surface a ¾-inch deal floor laid on thin tar is substituted, similar to some which we recollect being laid by your directions some ten years ago, and with which we believe there has never been any complaint as to vermin or rot, there would be an additional cost of about 14*s.* 6*d.* a square. We estimate the cost per square of the floor as per section at 4*l.* 10*s.* 6*d.*, or with boarded surface at 5*l.* 5*s.* a square. This particular flooring is lower in price than the usual fireproof floor, but upon its durability or other advantages it is not, as you intimated, our province to offer an opinion. We shall be happy to give any further information or details upon the matter.—We are, dear sir, yours faithfully,

"WILLIAM REDDALL & SON,  
"Estimating and Quantity Surveyors."

I have also placed in his hands a sketch of the same idea, but cheaper and doubtless not so perfect, but sufficiently useful to be often used. I also think that the wirework in lieu of lathing, as presented by Mr. Stent, of New York, and of which there is a model or specimen here, might be usefully applied to some of the ordinary floors, giving them some additional immunity from fire.

This question is, however, so serious and important, and so many men and so many minds are engaged in solving the many difficulties of the subject, that I am content to have started it, and now leave to the many eager and intelligent advocates of the various systems and theories, an enumeration of their views.

## SCHOOL BUILDINGS.

**Enfield.**—The foundation-stones of the new schools for the Edmonton Union were laid on the 19th inst. The schools will ultimately accommodate from five to six hundred children. The general scheme may be described as follows:—Entrance lodge next road; some distance in from road, right and left of the ground, two receiving wards; in rear, main building divided into several groups that floors or blocks may be isolated in cases of epidemics or fire, extension made with ease, and the character of a public school imparted, the children meeting for instruction and recreation and then filing off to different block or separate houses. The centre of the group contains master's and matron's quarters, committee room and bedrooms for servants, with stores, bakery, kitchen, dining hall, lavatories, bath, laundries, engineer's shop, boiler house and workshops, with boys and girls and infants' schools grouped round and connected by corridors. These departments overlook large playgrounds open to the sun; beyond is a broad road running transversely to the estate along the sides of which will be cottage homes, each home to have thirty-one children and two foster parents. In a distant part of the land is an infirmary made up of pavilions and more distant still from buildings. The infants' department have school-mistress and nurses' quarters in centre, boys and girls have chief master and mistress, and sub-master and mistress at either end. Taken as a whole the plan is different to that of any other school. The estate is forty-two acres in extent. The architect is Mr. T. E. Knightley. The builder, Mr. Charles Wall. The contract, 54,000*l.*

**Hammersmith.**—The fine building which has been erected for St. Paul's school was opened on Wednesday by the Lord Chancellor. The site contains about sixteen acres, and in consequence the building has been placed at a distance from the road, which allows of a display of its proportions. Brick and terra-cotta of a deep red colour were used for the walls, and the roofing tiles are of the same colour as the walls. The effect is most pleasing. The school is 350 feet in length. There are twenty-four class-rooms, each 30 feet by 24 feet, two large lecture theatres, and a hall at the west end measuring 80 feet by 40 feet. Laboratories, drawing schools, &c., are also provided, as well as a dining-room and kitchens. The house for the head master is close to the road, and forms a picturesque group. A cloister leads to the main building. In the rear of the school is a large playground with seven fives' courts, and a swimming bath and gymnasium will shortly be constructed. The school will eventually accommodate about 1,000 boys. Mr. Waterhouse, A.R.A., is the architect.

## CHURCH BUILDING AND RESTORATION.

**Bootle.**—On Sunday, the 20th inst., the foundation-stone of a Roman Catholic church to be erected, together with a presbytery, in Marsh Lane, Bootle, Liverpool, for the Very Rev. Dean Kelly, was blessed by the Bishop of Liverpool, the Right Rev. Dr. O'Reilly, in the presence of the Bishop of Trenton, New Jersey, U.S.A., and a numerous body of clergy and laity. The presbytery has accommodation for four priests, and the church, which is of large proportions, is designed in the style of the Early Decorated period, and built of local red sandstone, the wall facings being hammer-dressed. It has a spacious nave, aisles, and chancel, with carefully-arranged confessionals, and is 63 feet wide internally and 152 feet long. Messrs. Hadfield & Son, of Sheffield, are the architects, and Mr. W. Haworth is acting under them as clerk of the works. Messrs. G. Woods & Son, of Stanley Road, Bootle, are the contractors, their foreman being Mr. Bishop.

**Manchester.**—The corner-stone of the church of St. Agnes, Slade Lane, Longsight, was laid on the 19th inst. The plot devoted to the sites of the church and parsonage is triangular, the church standing at the base or northern side, and the parsonage on the south side of the church. The church, as now being built, will seat rather over 500 adults; but the scheme provides for an addition of 100 or more. The plan comprises a broad nave of four bays. Another narrower bay marked off from the wider portion by a pointed arch of two "orders" of mouldings. On the south side, at the south-west corner of the nave, is a spacious porch gabled to the south. At the centre of the west end is a semi-octagonal baptistery, with a tall-pointed arch opening into the church, and tall-pointed windows piercing three of its sides. The chancel—semi-hexagonal in shape at its eastern end—is raised seven steps. It has around the sides twelve arches, eight of them pierced with long-pointed windows, with stone-cusped heads, and four with panels only, with cusped and pierced circles above them. These window-cills are kept well up, and the space below them is panelled or arched in brick. On the south side there will be sedilia and a credence. The walls inside will be lined to about window-cill height with brown glazed brick, above this with yellowish bricks from Ruabon. The windows are framed, as it were, in red brick. The cornices and arches generally are of the same material; but the chancel arch has stone voussoirs alternating with the brick. The glazing is arranged to be in patterns of pale-tinted thick glass, with lines of brighter glass in the margin. The walls generally outside are to be of grey brick, with red for the framing in the windows and for quoins and other parts. The strings, labels, and moulded parts are of terra-cotta. Though there will be stone in pillars, capitals, and bases, and in cills and cusped heads of windows and elsewhere, the church is a brick one. It is designed by the architects, Messrs. Medland & Henry Taylor, in brick, and would not be suitable for erection in any other material. The foundations have cost under 150*l.* The superstructure, as above described, has been let for 2,700*l.*, with 112*l.* for additional cost of a wood block floor.

## NEW BUILDINGS.

**Haverfordwest.**—The Town Council of Haverfordwest have decided upon the erection of a public abattoir, according to plans prepared for the purpose by Mr. T. P. Reynolds, architect, Haverfordwest, which have received the approval of the Local Government Board. The site has been presented by Lord Kensington, M.P. The undertaking will be proceeded with without delay. The contractor for the building is Mr. Thomas Jenkins, of Telcomb, near Haverfordwest, at 1,560*l.*, and for the ironwork and machinery Messrs. A. Gardiner & Sons, of All Saints' Ironworks, Bristol, at 240*l.*

**New Oscott.**—The Princess Alice Orphanage has been opened. An estate of eighteen acres was purchased for 2,747*l.*, and when all the buildings are erected there will be accommodation for 300 children. At present only a part of the plan has been executed. The general plan of the orphanage is to have groups of separate cottage homes. Each will have its own enclosure of garden or orchard, and workshops will be erected for instruction in useful trades. The present part of the orphanage consists of the common hall, kitchen and servants' offices, board-room, administrative offices, and governor's house. When the whole scheme is carried out, twelve cottages will have been erected, six for boys and six for girls, each to accommodate a "family" of about twenty-five children. The building is chiefly of red brick, with tiled roofs. The architect is Mr. J. L. Ball, Warwick Chambers, Birmingham, and the work has been carried out by Messrs. Wilson & Son, Soho Hill, Birmingham.

**The Directors of Perry and Co. (Limited),** have resolved to pay on September 1, out of profits, an interim dividend on the ordinary shares for the first six months of this year at the rate of six per cent. per annum tax free, being at the same rate as for the corresponding period last year. The half-yearly dividend on the preference shares will be paid as usual at the fixed rate of 5 per cent. per annum, and free of income tax.

## GENERAL.

**Mr. Josiah Conder, A.R.I.B.A.,** architect to the Japanese Government, has obtained the Royal license to accept and wear the insignia of the fourth class of the Order of the Rising Sun, which has been conferred upon him in recognition of his services.

**An Exhibition of Paintings,** drawings, and engravings illustrative of ancient and modern Rouen will be held in the Musée Bibliothèque of the city during August and September.

**M. Daray,** a pupil of M. Guadet, has obtained the prize given at the end of the year to students of the Ecole des Beaux-Arts, Paris, for his drawings of a chimney-piece at Fontainebleau.

**An Industrial Art Exhibition** is to be opened shortly in Geneva. It will comprise works in metal, pottery, enamel, chasing, &c. If the experiment is successful it will be again repeated.

**Mr. O. L. Warner,** the American sculptor, has completed a statue of William Lloyd Garrison, the abolitionist, which is to be erected in New York.

**The Prize** which was founded by M. Deschaumes, to reward young architects, "vivant dans la plus parfaite union avec une ou plusieurs sœurs," has been divided between MM. de Sévelinque and Margotin. It amounts to 1,500 francs.

**Earl Nelson** will open the Art and Industrial Exhibition to be held in Newbury next September.

**Sir Edward Baines** has agreed to a request from the Mayor of Leeds to sit for his portrait which it is intended to hang in the Corporation buildings.

**Mr. D. W. Stephenson, A.R.S.A.,** has executed a life-size alto-relievo bust in marble of the late Canon Battersby, which is to be placed in the south aisle of St. John's Church, Keswick.

**The Annual Meeting** of the Bristol and Gloucestershire Archaeological Society commenced at Evesham on Wednesday.

**The Birmingham Art Gallery** has obtained the drawing *La Marseillaise*, by Gustave Doré; a landscape in oil, by Mr. F. W. Hulme; and a drawing by Mr. David Cox, jun., of *Greenfield*, the residence occupied for so many years by David Cox, at Harborne.

**An anonymous Donor** has offered 20,000*l.* towards erecting a building in Edinburgh for the joint accommodation of a National Portrait Gallery and a Museum of Antiquities.

**A Treaty** has been concluded between the French and Japanese Governments for the exchange of works of art.

**The Theatre Français** is about to acquire the statues of Molière by M. Caudron and Corneille by M. Falguère, which will be placed in the niches in the vestibule hitherto occupied by the statues of Rachel and Mars.

**A Plot of Ground in Melbourne** having a frontage of 16 feet and a depth of 130 feet has been sold for 13,120*l.* This is supposed to be the highest price paid for a building site in the city.

**A Faculty** has been granted for the enlargement of Christ Church, Clifton, on the condition that a bond for 2,000*l.* be lodged at the registry before the sealing of the faculty if the whole sum required for the contract is not subscribed.

**A New Vicarage** has just been commenced for the parish of Wick, near Bath. The architect is Mr. W. L. Bernard, of 39 Broad Street, Bristol, and the contractor, Mr. J. B. Hudson, of Yate, Chipping Sodbury.

**A Competition** was lately instituted by Messrs. Willing & Partners, Leeds, for the conversion of the old Corporation Gas Offices, Boaz Lane, into an hotel, restaurant and bodega. The designs of Mr. Nelson, architect, Leeds, have been awarded the first, and those of Mr. James Ledingham, architect, Bradford, the second premium. Mr. Watson, architect, Leeds, was the referee.

**Drury Lane Theatre,** having been re-let to Mr. Harris for a further term of five years, is to be repaired and decorated at the expense of the lessee. The rent is 6,000*l.* a year, with an additional sum of 10*l.* for every extra performance.

**The Arboretum in Walsall** has been acquired by the Corporation at a cost of 4,600*l.* Reed's Wood, containing forty-six acres, has also been bought, and a site for a Science and Art Institute in Bradford Street.

**A Strike** of five thousand bricklayers, with their labourers, has taken place in New York for a reduction of the duration of the day's labour to nine hours. The majority of the employers yielded at once, as the strike, if protracted, would stop the work on many new buildings.

**Messrs. Robert Boyle & Son,** 64 Holborn Viaduct, E.C., and Glasgow, have recently applied their system of ventilation to the headquarters of the Honourable Artillery Company, Finsbury; Liberal Club, Sheffield; Burton Club, Burton-on-Trent; County Hall, Menai Bridge; Franciscan Convent, Bridgwater; New Lecture Hall, Newcastle-on-Tyne; Bromley and Beckenham Joint Hospital; New Public Baths, Lewisham; London and County Bank; St. Austell Union; Hull Workhouse, Hull; New Workhouse, Wandsworth; Richmond Union, Surrey; Hanwell Police Station; New Police Station, Mitcham; H. M. Prison, Leicester; and H. M. Prison, Manchester.

# SUPPLEMENT

TO THE

# ARCHITECT.

## CONTRACTS, COMPETITIONS, AND TENDERS.

LONDON, JULY 26, 1884.

### TENDERS, ETC.

\* \* As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, 175 Strand, London, W.C., not later than 3 p.m. on Thursdays.

\* \* Correspondents, when writing to notify an extension of time, or an alteration of the date of sending in Competitions or Contracts, are requested in their letter of advice to write at the head of the required change—  
"Contract Supplement to THE ARCHITECT."

### ADVERTISEMENT SCALE.

### COMPETITIONS OPEN.

NORTH SHIELDS.—Aug. 18.—Plans are required for Alterations and Additions to the Workhouse. Mr. Christopher Scott, Guardians' Hall, North Shields.

### CONTRACTS OPEN.

ASHBOY.—July 26.—For Building Schools. Mr. W. Hague, Architect, 62 Dawson Street, Dublin.

BANBURY.—August 5.—For Building Three Shops and Cottage. The Banbury Co-operative Industrial Society.

BELFAST.—For Additions to House. Mr. John Malcolm, 14 Victoria Street, Belfast.

BELFAST.—July 28.—For Building Artisans' Dwellings for the Doagh Spinning Company. Mr. John Lanyon 1 Alexandra Chambers, Lombard Street, Belfast.

BERRY BROW.—For Building Chapel. Mr. J. H. Burton, Architect, Warrington Street, Ashton-under-Lyne.

BIRMINGHAM.—Aug. 28.—For Erection of Kitchen and other Buildings at the Workhouse. Mr. W. H. Ward, Architect, Paradise Street, Birmingham.

BRAMCOTE.—For Building Schools. Messrs. W. & R. Booker, Architects, Short Hill, Nottingham.

BROMLEY.—Aug. 13.—For Construction of Cant Clough Reservoir and Works in connection. Mr. E. Filliter, 16 East Parade, Leeds.

CLIPSTON.—For Restoration of Church. Rev. C. F. Blyth, Clipston Rectory, Northampton.

COVENTRY.—Aug. 6.—For Rebuilding Premises. Mr. T. W. Whitley, Architect, Bank Chambers, Coventry.

DARLINGTON.—For Additions to Property in Bondgate. Mr. Francis Parr, Architect, 6 Duke Street, Darlington.

DENTON.—For Building Villa Residence. Messrs. T. D. & J. Lindley, Architects, Henry Square, Ashton-under-Lyne.

EAST MOSELEY.—For Building Wesleyan Sunday-school. Mr. Charles Bell, Architect, Dashwood House, 9 New Broad Street, E.C.

ELLAND.—July 28.—For Building Four Cottages. Mr. John Mortimer, Architect, Elland.

GROSMONT, WHITEY.—Aug. 1.—For Completing Tower and Spire of St. Matthew's Church. Mr. Charles Noel Armfield, Architect, Whity.

HALIFAX.—Aug. 1.—For Building House. Messrs. Leeming & Leeming, Architects, Northgate Chambers, Halifax.

HERNE BAY.—For Building Wesleyan Church. Mr. C. Bell, Architect, Dashwood House, 9 New Broad Street, E.C.

HINDLEY.—For Building Eight Dwelling-houses. Messrs. H. Walls & Son, Surveyors, 8 King Street, Wigan.

HORNSEY.—July 31.—For Additions to Local Board Offices. Mr. T. de Courcy Meade, Surveyor to the Local Board, Southwood Lane, Highgate, N.

HUDDERSFIELD.—July 31.—For Additions to Armitage Bridge Mills. Messrs. John Kirk & Sons, Architects, Huddersfield.

HUNSLLET.—Aug. 1.—For Building Twenty-two Houses Mr. John E. Leek, Architect, Hunsllet.

INCHBROOM.—Aug. 1.—For Bridge over the Lossie (Mac'onry and Ironwork). Mr. H. J. Mackenzie, C.E., Elgin.

LITTLE CHART.—July 28.—For Building House at Paper Mills. Mr. Luke Langley, Estate Agent, Little Chart, Ashford.

LONDON.—Aug. 4.—For Building Fire Brigade Station, Bishopsgate Street. Mr. J. E. Wakefield, Metropolitan Board of Works Office, Spring Gardens, S.W.

LONGLANDS.—For Erection of Farm Buildings. Messrs. Powell & Grant, Architects, L'andloes, Montgomeryshire.

LOWESTOFT.—July 29.—For Building Warehouse, Raglan Works. Mr. W. B. Cockrill, Architect, Glencoe House, Gorleston.

MACCLESFIELD.—Aug. 2.—For Building Boiler House and Supplying Boiler. Mr. G. H. Corbishley, Secretary, General Infirmary, Macclesfield.

MIDLAND RAILWAY.—Aug. 1.—For Repairs and Painting to Station Buildings at Calverley, Normanton, Cudworth, and Barnsley. Mr. A. A. Langley, C.E., Engineer's Office, Derby.

MOUNTAIN ASH.—Aug. 5.—For Extension of Miskin Schools. Mr. Moses Cule, Architect, Pentrebach, Pontypridd.

MYNYDDISLWYN.—July 29.—For Building School and Teacher's House at Crumlin. Mr. E. A. Lansdowne, Architect, 26A High Street, Newport.

NEWBURY.—Aug. 4.—For Building School and Master's House for Governors of St. Bartholomew's Grammar Schools. Mr. J. P. Power, Architect, 67 Basinghall Street, E.C.

NEWQUAY.—July 31.—For Building Three Dwelling Houses. Mr. A. S. Clunes, Architect, Fowey.

NORTHAMPTON.—Aug. 6.—For Repairs and Reseating Church. Mr. E. Ashworth, Architect, Exeter.

PLYMOUTH.—Aug. 5.—For Building Wing to Female Orphan Asylum. Mr. James H. Keats, Architect, Courtenay Street, Plymouth.

PRESTON.—Aug. 20.—For Construction of Dock, Tidal Basin, Locks, Diversion of River, &c. Mr. E. Garlick C.E., 33 Winckley Square, Preston.

SHIPLEY.—July 28.—For Building Chapel Keeper's House, Class-rooms, &c. Mr. S. Wright, Architect, Church Street, Windhill.

SMETHWICK.—July 31.—For Building Mortuary. Messrs. Harris, Martin & Harris, Architects, 119 Colmore Row, Birmingham.

SOUTHAMPTON.—For Alterations to Church of St. James. Mr. Mitchell, Architect, 8 Portland Street, Southampton.

STONEFOLD, HASLINGDEN.—For Building Proposed Church. Mr. E. L. Pain, 19 Buckingham Street, Strand, London.

SWANSEA.—July 28.—For Building Shops and Premises. Messrs. James, Seward & Thomas, Architects, Castle Buildings, Swansea.

WELLINGTON.—Aug. 2.—For Building Town Hall and Additions to Markets. Mr. E. T. Howard, Architect, Wellington, Somerset.

WEST VALE.—July 28.—For Building Sunday School. Mr. W. H. D. Horsfall, Architect, Albany Chambers, Halifax.

WOOTTON BASSETT.—Aug. 1.—For Erection of Cattle Shed and Yard at Manor Farm, Broad Town. Mr. Richard Darley, Architect, Chippenham.

WORTLEY.—July 28.—For Erection of Schools, Out-buildings, and Boundary Walls. Mr. R. L. Adams, Architect, Imperial Buildings, Bond Street, Leeds.

### TENDERS.

#### ASHFORD.

For Rebuilding No. 77 High Street, Ashford.	Mr. W. R. King, Architect, 22 Bank Street, Ashford.	Quantities supplied.

## IMPROVED PATENT REVERSIBLE TREADS & LANDINGS

### FOR EVERY DESCRIPTION OF STAIRCASE.

THIS Patent is an improvement on the well-known wooden block construction, and its speciality is that the wooden blocks in each Tread can be removed and transposed so many times that it is almost indestructible besides being noiseless.

No. 3.—Section of Tread showing Iron Risers.

No. 6.—Sect. of Worn Stone Step nosed with Patent Tread.

No. 8.—Section of Tread reversed, the worn portion underneath, and new face presented for traffic. In this case the original level is maintained by iron grids that fit into the channels on the underside.

In Hospitals, or places where it is desirable to be free from dust, the blocks can be placed close together, not leaving any cracks, so that the treads or landings can be swept or washed quite clean; also, if it be necessary to get light under a Staircase or Landing, rough glass blocks can be fitted in the Iron frames, side by side with the wood, and a subdued light thus obtained.

Each Tread is so constructed that the wooden blocks of which it is composed can be removed by taking off the brass or iron nosing of the tray, so that when the outer edge of the wood is worn, the blocks can be taken from the front and those next the riser (which will be quite intact) substituted. The worn blocks, after being reversed, are slid into the position next the riser. This at once gives the tread the appearance of being quite new, and ready for prolonged wear. When in their turn the nosing blocks again become worn, the same operation can be effected by transposing the unused blocks from the sides of the tread to the front, and so on until all are in turn utilised. Finally, when in the course of years the wood is worn out, the trays can be re-filled at a very small cost; and if they should not require entire re-filling, can be re-nosed with new blocks for a few pence. Skilled labour is not required in removing or transposing the blocks. These advantages are so obvious that remark is superfluous, and the many years the Wooden-block Treads have proved their efficiency, places the durability of this construction beyond doubt. It has already been adopted by some of the leading Architects and Engineers. The Patentee generally uses Oak, Elm, or Teak, in these Treads, but, if an exceptionally durable Staircase is required, employs "Jarrah" (an Australian mahogany of extreme hardness), samples of which will be sent on application.

The Trays which contain the wooden blocks can be made of either wood or cast iron, the latter being, of course, superior. In either case they are in themselves complete, and only require wood or iron stringers to make a finished staircase. If necessary they can be constructed with strong lugs to build into wall, and fix like ordinary stone steps, only being less than one quarter the weight. In this case the balusters are fixed in sockets cast on the outer edge of trays. Particulars to be obtained from the Patentee, at the Works,

# The Architect.

## THE NEW ADMIRALTY AND WAR OFFICES COMPETITION.

THE final award in this great competition has now been made public, and concludes with an unanimous recommendation that, subject to the approval of Parliament, Messrs. LEEMING & LEEMING, of Halifax, be employed as architects of the new building for the above-named offices, they being considered to have produced the best design. We are quite sure that not only will our readers heartily congratulate these architects on their well-earned success, but that all of them who belong to the profession of architecture

will also congratulate themselves that in this instance, so far as it lay in the power of the judges to secure it by their recommendation, the best men are to win not mere distinction or a small money premium, but the actual prize which is the real object of a competitor's ambition. It was not so in the great public competition for Government offices which resulted in Sir GILBERT SCOTT'S employment to build the Colonial Office; and it cannot have been said to have been so in the Law Courts competition; nor, indeed, are the successful competitors in the present case safe from the many chances and changes which beset all public works; but still we repeat the judges have done for them all that it lay in their power to do, by selecting without any qualification one design for adoption, and, by recommending with equal distinctness that the authors of that design be employed as architects.

We confess to some gratification at the position occupied, and, so far as we remember, occupied for the first time, by the professional men who took part in the adjudication. They were not assessors, or advisers, or paid experts, but acted and signed the report as judges, just on the same footing as the First Commissioner of Works himself. Their services were entirely honorary; that is to say, they will receive no professional fee, but they have the reward, which to such men is not a small one, that in their persons the profession with which they are identified has been treated with due respect; nor should it be passed over as an additional recognition that members of the two architectural societies are to share with Members of Parliament the privilege of private view during the last days of the present week. After this week, the not unnatural wish which has been repeatedly expressed that the designs should be publicly seen, will be gratified by their exhibition for a month.

Three designs are named in the report as having recommended themselves to the special notice of the judges. That by Messrs. LEEMING, that by Messrs. VERITY & HUNT, and that by Messrs. ASTON WEBB & INGRESS BELL. A short inspection of these designs, and a comparison of them with the six others not placed so highly, will soon show that the same thing has happened here which occurred in the Law Courts competition. The best plan was produced on that occasion by EDWARD BARRY, whose treatment of his design was not good; and the best elevation (or more properly the best liked, for the best was undoubtedly contributed by BURGESS) was that by STREET. The judges, it will be recollected, advised a partnership between the two, and it was only when Government perhaps wisely declined to hear of anything of the sort, and referred the matter back to them, that their choice fell definitely on STREET. The best plan in this competition will be found to be that of Messrs. VERITY & HUNT, and had their architectural treatment been more happy, there can be no doubt that they would have carried off the prize. The best exterior elevations, and, for the matter of that, interior elevations and sections, are those in the beautiful design of Messrs. WEBB & BELL; but the plan, though possessing some striking points was found defective, not to mention that the very great height to which their buildings are carried may in all probability have told against them. The judges have fallen back upon a design which, though extremely well planned, does not quite equal the best plan, and though full of architectural

merit is distinctly below the best in those indications of originality, power, and effectiveness which display architectural genius. Nor is it easy to see how they could have avoided coming to the conclusion which they have actually reached under the circumstances.

The site may be described as a large rectangle, the longest dimension of which runs north and south. A corner is parsimoniously cut out of this site at the north-east angle, so that the expense of buying BIDDULPH'S bank might be avoided, and a larger portion, rectangular in shape, is also cut out of its south-west corner, with the more praiseworthy object of not encroaching on the Horse Guards Parade. Messrs. LEEMING, in dealing with this irregular block, have made their main internal quadrangle oblong, its axis running east and west, and have provided no fewer than nine smaller internal open courts. They are enabled to light their corridors and staircases, which are designed with a liberal spaciousness, from these courts, and all the rooms of their building are lighted from the exterior or from the great central quadrangle. This management, coupled with good direct lines of communication, well-shaped rooms and well-disposed approaches, marks the plan out as a thoroughly studied one. The difficulty of providing the accommodation required in the way in which it had to be arranged is said by everyone who attempted it to have been immense; and as this design appears to provide what was required on a less number of floors than some of the others, and apparently without any departure from the regular system on which its lines are laid down, it is manifest that the most careful and painstaking study must have been unstintingly bestowed upon it.

The elevation towards Whitehall is the one which will be most seen, and which should probably be considered the principal one. To suit the exigencies of the plan the principal entrance cuts it quite unsymmetrically, and the difficulty has been dealt with by dividing this point into two portions. The northern part—that nearest Charing Cross—is marked off by two pavilions or low towers, having a considerable length of front between them. The more southerly of these towers forms the main public entrance, and it is in a line with the axis of the principal internal quadrangle. South of this portion of the front, and with the same general ordinance, comes a distinct symmetrical composition divided into three portions by two projecting bays, and terminating near the Horse Guards by a well designed tower, the principal one of the whole building. This elevation, it is proposed, shall rise from the edge of the pavement, with no setting back or even partial recessing, to a height of about 90 feet, surely too high even for the width of Whitehall, although a fairly wide thoroughfare. The front has four storeys, and a plainly rusticated basement. The ground storey is richly rusticated, and has square-headed windows, occupying arched openings with projecting piers between them. The first and second floors are united by a Corinthian order of columns standing on the piers just referred to. The openings differ to some extent on the two floors in this elevation, though hardly enough, and on the north side they are almost exactly alike. Above the entablature of the order comes an attic with square-headed openings and roofs of tolerable steepness, though not conspicuous enough. This arrangement of storeys, and the same general treatment of them, runs round the building, and with modifications is repeated in the quadrangle.

The elevation towards the Green Park is symmetrical, accentuated by two massive towers at the ends, with domical roofs, and happily broken up by four projecting bays, each carried up and crowned with an ornamental roof, so as to break the skyline. A similar treatment is employed on the south front, the one looking over the Horse Guards Parade, while the north front, more broken up by the disposition of the plan than the others, is rather less ornate.

The draughtsmanship, with the exception of the perspective view, is of the very highest degree of excellence; the human figure, whenever introduced in groups of sculpture or statues, is drawn with exquisite skill and taste; and all the ornamental details are equally well represented. We are far from considering that the design is faultless, and in such important matters as the position of the towers and the contrast of the masses of the building, we believe that further study may enable the architects to introduce improvements of importance; but we do not desire to seem ungracious or fault-finding at a moment when the difficulties of a most complicated problem have been successfully solved by the fortunate winners of this competition.

Messrs. VERITY & HUNT have grouped their buildings round a quadrangle that is nearly square, with one entrance from Whitehall and a second on the north from Spring Gardens. Nothing can exceed the simple straightforwardness of the arrangement, and the quadrangle is of an excellent shape. As in the prize design, numerous smaller courts admit light to the windows and staircases. The buildings show five storeys of square-headed openings, and depend on fenestration without an order for their architectural character. The style is a correct but rather heavy version of Renaissance, and the design would be extremely improved by the addition of high roofs; but it is far less happy in treatment than the one placed first, though, as has been said, masterly in plan.

The design of Messrs. ASTON WEBB & INGRESS BELL has a central courtyard of a cruciform shape, and a large amount of well-lighted wall surface has been obtained in this courtyard by their peculiar arrangement. Much of the lighting of corridors, &c., appears to us defective, and there can be little doubt that a critical examination of the plan by the judges has revealed other imperfections, for the artistic merits of this design are such that it must have been with reluctance that they gave it up. The style is French Renaissance of a rather early type, with high-pitched roofs. The buildings are lofty, showing six storeys as against Messrs. LEEMINGS' four; but, with excellent judgment, the principal part of the Whitehall front is recessed back some 60 feet, so that the full height would be well shown. Fenestration is chiefly depended upon, and arcades are to some extent introduced, but the happy distribution of the masses, the skill with which the skyline is broken, and the success with which towers are planted just where they tell best, are of the highest order of merit. The drawings are very artistically worked out, and a very careful internal perspective full of accurate and uncompromising draughtsmanship vies with a clever picturesque sketch of the skyline of the building, as seen from the distance. There will be a good deal of regret that the authors of this charming design are not to have the honour of enriching the architecture of this part of London by carrying it into execution.

A short mention of the remaining designs is all that we can attempt. That by Messrs. GLOVER & SALTER has a main quadrangle running north and south, and not very many smaller courts. The treatment is Gothic, and there is a large detail drawing, which shows much of the influence of WILLIAM BURGESS. An alternative drawing of one of the fronts, translated into Renaissance, is appended, and, we think, is even more successful than the Gothic treatment. No other competitor has attempted the Pointed style.

Messrs. HALL & POWELL have made the axis of their quadrangle east and west. This design is of fenestrated Renaissance, sober in character. Part of the Whitehall front is recessed. Their drawings are distinguished by cleverly-designed groups of sculpture in pediments and on pedestals, and excellently drawn.

Messrs. MAXWELL & TUKE have a great quadrangle, the axis of which is placed east and west, and two smaller ones parallel to it, a very natural arrangement of plan, and apparently well worked out. They also depend on fenestration, but the proportions of many of the features in their design seem to want greater height. Mr. PORTER, the only architect who competes alone, provides a large quadrangle placed north and south, and secures an open space next Whitehall by setting back his building. The treatment is hardly equal to the plan, especially as regards the skyline. The use of an order to each storey, somewhat in the manner of VIGNOLA, is more French than English in feeling. Messrs. SPALDING & AULD have provided one large quadrangle, of which the main length is east and west, and a smaller one parallel to Whitehall. The architectural treatment of their design is Palladian. Messrs. STARK & LINDSAY send what seems a carefully studied plan with a north and south quadrangle. The style adopted by them may be called Venetian Renaissance, and the design is rather rich. The Whitehall front is broken, and in that respect resembles to some extent the prize design.

We have no doubt this collection of plans will be largely visited during the time it is open, and though it is only in our power to congratulate the authors of one on complete success, we can cordially recognise that each competitor has gallantly and worthily striven for the prize. It is no small honour to have won a place in such a competition as this by the excellence of sketch designs. How elaborate and com-

plete even those sketches were, can be judged of by the visitor, as the preliminary drawings of the nine selected competitors are hung side by side with the worked-out plans in the room in Spring Gardens where the collection is to be seen.

### THE INFLUENCE OF ART ON HEALTH.

PLAIN people—who are right in the main, although not always—have a notion that health is a simple sort of goddess, eating and drinking wholesome food, wearing good clothing, breathing fresh air, taking as much exercise as may be convenient, and avoiding draughts. In this age of exhibitions, certain ingenious persons have conceived the idea, and therefore, have very well carried it out, of developing the *cultus* of health at South Kensington, on what is certainly a much broader basis, and in some degree, indeed, a considerably ornamental one, extending sufficiently far all around the subject of devotion as to embrace such paraphernalia as the hatching of salmon fry, and the performance of Chinese music. Architecture, as all the world must know, could not have been excluded from the programme, and distinguished designers of the houses we live in have discoursed, therefore, on the mysteries, not only of drains and ventilators, but of arsenical wall papering, and the smoking of chimneys. Amongst the rest it has been hinted that even what the plainest of our plain people would call the looks of things may be taken to have some influence upon bodily well being. Can this be so?

At any rate, the question of the effect of artistic influences upon our bodily health is one that is not to be put off with a deferential but incredulous smile. Not only are we studying more carefully, and understanding more clearly, the intricate elements of human organisation, but we are becoming every day more keenly susceptible to the thousand-and-one agencies which affect in particular what we call our nervous system. The more we discover about the delicate piece of mechanism which we call a man or woman, the more freely at the same time are we getting into the way of putting it on its mettle. What with morning, mid-day, and evening newspapers, the continual exercise of penny posts, electric telegraphs, telephones, uncanny instruments that spin out of themselves long ribbons of printed gossip from all over the world in quiet entrance halls, and a hundred other demoniacal incentives to fidgets, a tithe of which would have driven our respectable grandfathers out of their seven senses, the wonder seems to be how we survive for any length of time the unrelenting assaults upon our nervous integrity. Well, all that need be said is that mechanism so artificially worried ought to be in some artificial way from time to time pacified, soothed, cooled, or otherwise restored to its normal quiescence, if it is really as a rule to withstand the strain. Not to speak of anything else, may we not at once affirm that, amongst the sedative and curative agencies thus coming to be so much in request, if certain classes of Englishmen, Americans, and others, are to keep their hair growing on their heads and their heads standing on their shoulders, the influences of art offer themselves with all seriousness as important promoters of private and public health.

It was observed at one of the recent meetings at South Kensington that colour, for one thing of this sort, has a direct influence upon the nervous system; and perhaps this is a very fair example of the effect of art in general—or ornamental art at any rate—upon what we are pleased to call the mind; for, manifestly enough, it is colouring harmonious or melodious that must be referred to, as against colouring inharmonious or unmelodious. This phraseology, indeed, suggests at once an interesting analogy that surely may be said to exist between colour-art and music. Perhaps it is near enough to the truth of yet mysterious matters if we say in very familiar terms that music operates by producing a certain vibration (for want of a better word) in the nervous system, the harmony and no less the melody of its movements being identifiable with some concurrence in this vibration, and the want of such concurrence being discernible as discord or dissonance. So also, no doubt, it is some other and probably more delicate vibration of the same nervous organism by which the pulsations of light in the universal ether, as in the former case the pulsations of sound in the atmospheric air, that produce the phenomena of consciousness which are spoken of as the effects of colour. If so, this follows: just as we well know that the difference between good music and bad

may be, to a highly-nervous temperament, the difference between delight and despair, so also the difference between colour-melody or colour-harmony and colour-horror may be, to a like highly strung sensitiveness, the difference between infinite pleasure and insufferable pain.

To carry this argument a little further is enough, and we are led to conclude that, in as far as abstract pleasure and pain are to be identified with abstract health and disease, the arts of the beautiful must connect themselves very directly with the health of man. That our mental pace is increasing rapidly in these days will be admitted without argument, and the time may come, for instance, when the nightmare produced by a dreadfully bad song shall drive an æsthetic enthusiast to suicide. It need not be supposed that there is any exaggeration here; and then we say that, as with the song, so with some "arrangement" in sky blue and scarlet, and so also, each in its degree, with the design of a wall-paper or a carpet, the modelling of a fictile ornament, or the cut of a dress. Art is art one and indivisible, and its influence in one thing is its influence in everything.

The extraordinary manifestations of unusual sentiment and emotion which have for some years back been regarded with so much enthusiasm by æsthetic admirers, and with so much astonishment by the more numerous classes of more composed enjoyers of the graces of the arts, are one of the peculiar mental phenomena of our England. It is idle to treat them with a laugh; that is not any sort of criticism. Whatever principles may be at the root of the development, principles there must be, and, much as some of us may be inclined to doubt the fact, such principles are worthy of being understood, if not worthy of being acted upon. Not only so, but they are entitled to rank as historical and indeed philosophical principles, the cause of whose coming to the fore may long remain undiscovered and undiscoverable, but whose function is nevertheless determined, if we could see as much, by necessity, and not merely by justifiable eccentricities. Perhaps it may help us to look in the right direction for understanding if we take our stand upon the question of the mental health of the people, in whole or in part. As instinct, according to our common formula, leads an earnest and serious party amongst us to seek relief somewhere from commonplace devices of which we have almost all learnt more or less to lament the ascendancy, this is quite enough to excuse both excess and error, so long as human nature remains what it is. The public are in search of artistic health, and must do as they can to find it.

This health may no doubt be found in two very different directions. In one we find repose, in the other excitement. Repose may of course be sleep, and excitement may be agitation; but even this distinction does not help us much, for repose may be all the worse for the patient and agitation all the better, and perhaps it is useless to inquire which is at the moment the panacea for the public ills. We cannot even speak of a *via media*; and perhaps the only reflection that is really worth anything is that nature may safely be let have its own way. In other words we may leave the principles of development which govern all things to be originated by their unknown causes and to produce their unknown effects.

## WESTMINSTER HALL.

(Continued from page 49.)

WITH regard to the towers flanking the north end of the hall, Mr. PEARSON remarks:—

The earliest record of towers at the north end is in a plan in the Crace collection at the British Museum, by Norden, date 1593, but there is no sufficient suggestion of their form to gather any clue as to what that originally was, and late drawings show them substantially as at present, but without battlements. In Hollar's print, on the other hand (1647), battlements are shown.

The alteration of these towers, therefore, cannot be based upon any reference to history or past record. But it is almost demanded by the extreme ungainliness of the existing front. This ungainliness is to a large extent due to the contiguity of Sir Charles Barry's buildings, the roof of which overtops the eastern tower, and has to be stopped in the most unfinished manner. It is said that Sir Charles Barry fully recognised this, and proposed in consequence to raise the entire hall floor and roof about 10 feet, and thus give it proper importance.

No part of the existing stonework which cases the front is earlier than 1820. The battlements are modern, and the large niches in front are conjectural restorations of what existed before.

It is certainly hard to believe, also, that the present windows are copied from anything of Richard II.'s time.

The whole front in fact has an air of spuriousness. I propose therefore to alter the windows and raise the towers one stage, which, to preserve a domestic character, will include two floors, and I have endeavoured to redesign this so as to harmonise Sir Charles Barry's elaborate architecture with the severer work of the hall. By thus remodelling them, I hope to render them worthy of their position and importance in the group in which they now play so insignificant and discordant a part.

By this reasoning, Mr. PEARSON's tender conscience, and fears of the reproaches of his predecessors hereafter, are laid to rest; and he has at last allowed himself to express his own feelings; still always with due regard to those of RICHARD II. on the one hand, and Sir CHARLES BARRY on the other.

We, however, feel compelled to look on the matter from the points of view of the present and the future, and not of the past, and have again to ask, *Cui bono?*

The one prominent characteristic of the hall is the simple majesty of its form and proportions as a hall, and this is conveyed externally by the prominence and scale of its gables, particularly from the north end, and this would be the only means were its flank to be hidden again behind a cloister.

The towers, by whomsoever they were built or recased, have been kept subordinate, and rightly so, for this very purpose; and to raise them considerably would destroy the prominence of the north gable and the character of a hall. The composition would then assume the appearance of the west end of some ecclesiastical building, and as such would be dwarfed by its far more grandiose neighbours. The towers could never assert themselves as towers, in close contiguity to the Clock Tower and others of the Houses, the Abbey, and St. Margaret's. With extreme reluctance, therefore, we are compelled again to dissent from Mr. PEARSON's proposals, for though we admit that the end of Sir CHARLES BARRY's building, rising somewhat higher than the adjacent north-eastern tower, is unfortunate, we feel convinced that the remedy proposed would be worse than the disease sought to be cured.\* If the details be "spurious" they are not obtrusively obnoxious, though doubtless some of the alterations in the fenestration proposed by Mr. PEARSON might prove desirable improvements.† "Old drawings," Mr. PEARSON says, "agree in showing the hall wall battlemented, and I have, therefore, unhesitatingly adopted this treatment;" and, again, "the dormers in the roof being modern and interfering much with the external and internal effect, I propose to remove." That is to say, that the missing features of the old work are to be replaced according to the most careful but still somewhat conjectural method of restoration, and any modern work removed. This is no doubt an excellent canon to follow as a rule, but we have shown what would be the result if carried out to the extent of reproducing buildings for which the use has passed away, and which never could have been ornamental. The side of the hall certainly lacks height, dignity, and richness under the present circumstances, when it has been brought so much more into prominence than was contemplated at the time of its erection. The parapet is gone, and Mr. PEARSON even cannot find out what it was; why, if it need to be rebuilt, as it does, should it be done as meanly as some old drawing indicates it probably was? Here, where a grand feature is wanted to give additional dignity to the hall without altering its general character, a compromise between the implied wishes of RICHARD and Sir CHARLES BARRY might be arrived at by a richer parapet, and covering the roof with lead; the dormers, being found to injure the internal effect of the hall roof, must, it seems, be dispensed with.

We sincerely wish we could have felt justified in supporting Mr. PEARSON's designs and proposals, for though we have come to different conclusions from himself from the data he has so carefully collected, we fully recognise the ability shown by his report and the accompanying drawings. We can thoroughly recommend them to the study of our readers for their intrinsic interest, and they should be preserved as a most full and complete record of the numerous vicissitudes which this remarkable building has undergone. At the same time,

\* Sir Charles Barry proposed to raise the hall bodily some 10 feet, and carried out the wing abutting upon it in a line with the rest of his façade with this view; and consequently, at its junction with the north-east tower, the former rises just 10 feet above the latter, but in rear of it.

† In some cases they would not. The large end window of the hall would be positively injured by the addition of the florid crocketed label proposed to be added.

having recently examined the ruins westward of the hall with some care, we are bound to say that we think Mr. PEARSON has misread some very important features, and in particular those upon which he has built up his theory that the original cloister was of two storeys. Upon one buttress there is the return of a parapet at the top with numerous small details, which, together with the course of moulding of buttress into which it is housed, is obviously a later interpolation, and probably part of some isolated small additional structure built for some special purpose there. We note that Mr. PEARSON does not in his proposed parapet restore its details nor even replace it in the same position or at the same level. Where then is its archaeological value? That it has not architectural value we are convinced.

We shall in conclusion make a short abstract of the history of the hall, as elucidated by Mr. PEARSON's admirable and voluminous researches.

EDWARD THE CONFESSOR founded, and WILLIAM THE CONQUEROR enlarged, the Palace of Westminster, but Westminster Hall was originally erected by WILLIAM II. (RUFUS), in the year 1097. What this first hall was the late removal of the Law Courts has rendered it possible to gain some definite idea. A continuous arcade, "after the manner of a triforium," was carried round the hall in the original design, but at some later date, during the time of the Normans, this arcade was interrupted at irregular intervals by a series of large window openings. In this alteration previously existing work, as far as it would go, was re-used in new positions, and small shafts, bases and caps displaced from the continuous arcade were replaced in two tiers to gain height for the taller windows, and where old work failed for the purpose, as for inner archivolt and external carved caps, that which was added betrays a later date. It had doorways at the north and south ends of the west wall, and three in the north end wall. There is no evidence to show how this Norman hall was roofed or lighted before the intrusion of the later windows described. Other repairs and alterations were probably effected, possibly by THOMAS A BECKET in the reign of HENRY II., and again others in that of RICHARD I. Then, in the period of that great patron of architecture and the fine arts, HENRY III., extensive works of construction and decoration were undertaken, but in the reign of EDWARD III. a great fire occurred, reaching as far as the Abbey, and no doubt extensive damage was done to the miscellaneous buildings, whatever they were, westward of the hall; and the fact recorded, that Parliament had to adjourn after the fire, implies that the great hall itself had somewhat suffered as well. Reference, also, is made to new works in connection with the hall in this reign, but in that of RICHARD II., in order, in all probability, to make it more suitable as a Parliament House, RICHARD entirely transformed it into the shape in which we see it at present. "The walls were raised two feet, and recased, and new windows were inserted. The existing roof was added, a new northern porch and towers and the large buttresses lately uncovered were built. Also 'divers lodgings' on the west side; these were mostly contained by a wall erected parallel to the hall, and connecting together the new great buttresses. The two tiers of wall arches between the Norman buttresses were also erected at this period." Further repairs were made by RICHARD III., and in the reign of HENRY VIII. another great fire occurred, which destroyed a large portion of the palace, which was never rebuilt, and in consequence of this damage, HENRY VIII. removed to Whitehall in 1529. In the time of ELIZABETH large further additions were made to the west side of the hall. In CHARLES II.'s reign Sir CHRISTOPHER WREN made sundry additions, and in that of GEORGE II. WILLIAM KENT built Courts of Common Pleas, and made a doorway on the west side, and also committee rooms along St. Margaret's Lane. Some of ELIZABETH's work was demolished, and St. Margaret's Lane widened in the time of GEORGE III., and in that of GEORGE IV. Sir JOHN SOANE demolished old work and erected his Law Courts. The north end was restored by THOMAS GAYFERE, mason to the Abbey, in the reign of GEORGE IV., and in that of WILLIAM IV. the walls of the great hall by Sir ROBERT SMIRKE, and finally, now in the days of VICTORIA, we have witnessed another great demolition and are awaiting proposed additional building.

Out of this inextricable maze it seems to us a hopeless task to pick out and restore the condition of any precise period, and we would ask in conclusion why now for the first time such a method of proceeding should be adopted?

In every other age but little thought was taken of what had been done before, other than economy and convenience might dictate, and those demands of convenience were sometimes necessarily of a mean character. We have learned to be more reverent to, and careful of, the architecture of the past, but regard to that must needs be subordinated to the wants of the present; and as those wants, from the causes we have explained, are no longer for comparatively paltry appurtenances to the majestic building which has at last become revealed, we are free to consider the problem almost entirely from its æsthetic side, with due but not more than due regard to the archaeological; and we trust that it will be in this spirit that the subject will be approached by the House of Commons. The sides of the hall were never intended for general view, and their remains can only be treated as curiosities. If they are to be religiously preserved as such, it must be within a court, formed possibly by building what we understand is much needed, viz. a range of committee rooms to the west of the hall.

We should much regret the necessity for this upon the æsthetic grounds we have given, but doubtless even such must give way, if need be, to practical requirements; and Sir CHARLES BARRY certainly did intend such a range to be built. If the curiosities of these ruins need not be preserved otherwise than in such a record of them as Mr. PEARSON has prepared, supplemented we would propose by the aid of photography, then let the side of the hall now exposed be dealt with as architecturally best. As to this point we can only suggest that the consensus of opinion is that Mr. PEARSON has not yet grasped this problem. His present drawings should therefore be looked upon as preliminary ones, submitted upon approval; and we trust he may yet be commissioned to revise them, and ultimately allowed to carry out perhaps even a greater work, but at any rate one which will command general assent, and be worthy of his high and deserved reputation.

## ARCHITECTS' CONFERENCE AT THE HEALTH EXHIBITION.

THE closing meeting of the Conference took place on Saturday, the 12th ult., under the presidency of the Right Hon. A. J. B. Beresford-Hope, M.P.

Mr. BERESFORD-HOPE said he conceived it a great honour to take the chair at the meeting that day, an honour consequent on one which he should always look back on as a very great honour and success of his life, namely, the having formerly filled the chair of the Institute of Architects, and to this as one of their past officers he owed the honour of being put in this distinguished position that day. It was a right and a happy idea of the Institute to come forward and claim its own share in the Health Exhibition, for what could be the meaning of architecture if it were not the science of contributing to health, happiness, and longevity in the most permanent of all circumstances of a man's life, namely, his house? Clothes got shabby and food was consumed, but a man's house ought to be part of a man, of his family, and it might be part of the inheritance of his family; therefore it was for us architects to make our houses not merely beautiful and luxurious, but healthful; and in proportion as sanitary science became more and more exact, less and less experimental, more precise and certain, so did the responsibility, and it was a very heavy moral responsibility, rest more and more on us to be, with physicians, the ministers of health. In this exhibition there was one feature which he was sure like all of them he had very much enjoyed, though he had been still more puzzled by it—he meant Old London. The exhibition was meant to be an apostle preaching health, and they produced that Old London with all its exquisite picturesqueness as a proof of how delightful and how beautiful an unsanitary city could be, and when he went through its frowning gateway and saw the beautiful gabled houses exquisitely carved, that charming Mediæval row, its streets widening and opening out, what could all this mean but to show the humbug of health and the beauty of insanitation? He thought something more than this was wanted. Mr. Birch ought to have put himself in communication with some one in Bond Street to produce some such smells as the Mediæval town would have yielded. Instead of the smooth, flat roadway, there should have been, not a trout stream, but a stream of deep, chocolate-brown fluid as was usually found in the streets of our Mediæval cities; and instead of that smooth, hard pathway, there should have been that broken-up composition of many substances on which the people of those days had to tramp? As it was its beauty was evident, but its insanitation remained to be guessed. He had been exceedingly struck by a drawing of Mr. Brewer's, one which was exceedingly beautiful and exceedingly

sad. It represented a Mediaeval cathedral, with houses clustered round about it, but no sign of human life. It was a representation of a city desolated by the plague, a deserted city about the year 1508. In the middle of it ran a sluggish stream, with some broken steps down which the maidens went to fetch the drinking water. A little further on the stream lost itself under a low-browed archway, for it was the drain and common sewer of the city. It was a history in which one read of the sufferings which attended the long-continued plague by which the city was desolated and rendered empty. If those of their friends who were engaged in the promotion of health thought it was their only or chief duty to build sanitary houses, they forgot or overlooked half their duty. It was quite as important to carry health into existing buildings as to erect healthy buildings. It was not merely the misbegotten productions of the jerry builder that they had to put right, but some of the most stately and luxurious homes in the land. There were no more treacherous buildings than those of the last century, when mechanical contrivances had advanced so much, while chemistry and sanitation had not. Fifty years ago there was a house in the West End of London which was overhauled totally regardless of expense by its owner, a man of enlightenment according to the views of those days, a man extremely munificent and imbued with all the notions of high life in London as understood in those days. Among other things provided in the house was a service of hot water to all the chambers. In a few years the house changed hands, and his successor did not feel called upon to carry on this expensive and elaborate system without an adequate return; so years went by, and all about it was forgotten. By-and-by, strange smells were perceived, and people felt strangely depressed in some of the rooms; and on an investigation of the house being made this disused hot-water service was discovered, and found to be a system for diffusing sewer-gas fresh and rich from the mains into the house. The hot-water service was laid, no doubt, by one of the first engineers of the day, but the simple fact that gas was gas, and that gas did rise, never occurred to anyone. Whenever persons bought or hired or inherited a house, let them first of all things look out for the lost and forgotten and hidden drains and cesspools. He spoke from experience within a limited area, but with so wide an experience within that limited area that he could say that the number of these was enormous, and the mischief they were doing incalculable. If search for a few of these forgotten things were set on foot, he believed the death-rate in the country would be notably diminished.

Mr. G. Aitchison, A.R.A., then read a paper on "The Sanitary Aspect of Internal Fittings and Decoration."

Mr. W. White, F.S.A., followed with a paper on "The Hygienic Value of Colour."

Mr. Cutler read a paper supplementing the two previous papers, and agreeing with them.

Professor KERR, on being called on to speak, said he was quite unprepared to discuss the subjects which had been so well treated by his friends Mr. Aitchison and Mr. White. Mr. Aitchison advocated the avoidance of dust and Mr. White advocated the introduction of colour, and it seemed well worthy the attention not only of architects but of those in command of architects—viz., the public—to consider what architects could practically do in the prevention of dust and the introduction of colour. Architects, he feared, could do little to keep dust out of the house, but once it had got in they might do something. The use of carpets, curtains, and upholstery was—within reason, and without going too far in this direction—to be discouraged, and we ought to consider whether we were not using too much upholstery in our rooms. The architect could do something in respect of decoration and projections, but not much as regarded polished surfaces, for the public generally did not like polished surfaces; but in his opinion, as far as they could be used, they should be used. Clients could not be expected to hold with all the suggestions of science. Over and above all, so much depended on the cleanliness of the housemaid. Certain cottages were to be seen in the country where everything was dirty, and certain other cottages, inhabited by the same class of people, where everything was clean as could be. Ladies, he thought, must look after this; for, if they would, they could keep the house clean. Professor Kerr concluded with some remarks on Mr. White's paper and the use of colour, and observed that the public were becoming nowadays more alive to a sense of colour.

Mr. EWAN CHRISTIAN said that there were some London streets he never would go through owing to the miserable effect of the horrible colour and aspect of the houses, and yet some people wondered why they felt depressed in them. As regarded the interior of our houses there was little doubt that what Mr. White had said was perfectly true: He himself had ordered one of his rooms to be papered with a crimson-flock paper, and on his return after a short absence he found he could not stop in the room half an hour, and he never went into the room again until the paper had been taken off. Woe betide, he said, anyone who put linoleum over a boarded floor. The floor would rot away in a year or two. The very best floor he ever knew perished in three years' time. Mr. Christian finished by an allusion to the value of flowers, and said that the presence of flowers in a cottage window was generally an

index of the cleanliness of the inmates, and consequently of the interior of the houses.

Mr. ROWE (of Sydney), said he was astonished to find that the upper sashes of the windows of the hotel where he was stopping would not open. He judged from this fact that probably thousands of the London houses were the same. He thought that it should be made compulsory on landlords to rectify such an unsanitary custom.

Mr. H. H. STANNUS said that a practice which obtained in Lancashire and Yorkshire had not been mentioned, not to fasten the floor boards till the house had been plastered. The house was the drier in consequence of the through draft, and there was not the same danger of dry rot. It was a custom which might well be adopted in the South of England. Where carpets were used dust accumulated, and whatever tended to increase the difficulty of taking up carpets to shake them increased the insanitary state of a house. He would always like to see the furniture of rooms fitted with large castors, so that servants might have no excuse or difficulty in getting up the carpets to shake them. When he found that Mr. Aitchison's paper treated of sanitary matters, and Mr. William White's of colour, he was astonished, and thought that matters had rather mixed. Thanks were due to each for entering on a new rôle and giving them the benefit of their counsel. As to the colours mauve and magenta, he hoped some one would appear who would be able to harmonise the two colours. Every fresh addition to the palette had been attended with difficulty, but in the end some one had arisen who had harmonised them.

After observations from Mr. Birch, Sir Joseph Fayrer and Mr. Charles, Mr. Beresford-Hope wound up the discussion, and said that in the house of his father, who was one of the first pioneers in art decoration, all the floors were of parquet or cement mosaic, which Mr. Aitchison had not referred to. This, which was an inheritance from the Romans, was still preserved by the Italians, and it was impervious to wet and afforded no harbour for dust. Of late there had been an enormous artistic development of tiles, and in this, he thought, we might have a beautiful, artistic and æsthetic architecture of the future.

Mr. T. H. Watson then read a paper on "The Collection, Storage, Management, and Distribution of Water for Domestic Purposes within the House."

This was followed by a short discussion, and the Conference broke up.

## THE SCOTTISH ART UNION.

THE annual meeting of the subscribers to the Royal Association for the Promotion of Fine Arts in Scotland, was held on Saturday last, in Edinburgh, under the presidency of Lord M'Laren, when the following report was read:—It is very gratifying to the committee to be able to report on this the fiftieth anniversary of the Association, that 947 members have been enrolled during the year just ended in excess of the previous year, and that the total fund subscribed amounts to 3,539*l.* 3*s.* The Association—the first established in the United Kingdom for similar purposes—was instituted in 1833, with a view to advance the cause of art in Scotland by affording encouragement to its professors. During the half century which has elapsed since the Association was instituted, its objects have been advocated and promoted by many illustrious men, and have met with a large amount of encouragement and support from numerous and intelligent classes of the community. Besides encouraging and fostering a love for the fine arts in general, the Association has undoubtedly helped to produce throughout the country not only a greater knowledge of art, but also a much greater interest in its progress. For some years prior to 1833, the date of the establishment of the Institution, the whole sales effected at the annual exhibition of the Royal Scottish Academy only averaged about 300*l.*, while paintings to about the value of 100,000*l.*, have since that year been purchased by the Association from the Academy. The manner in which the public has evinced its confidence in the mode in which the affairs of this Association have been carried on is shown by the large sums annually subscribed towards the objects for which the Association was instituted. These sums amount in all to upwards of 235,000*l.*; and have been applied by the various committees of management in the purchase of paintings and sculpture for the members, in the production of engravings and illustrated works for circulation amongst the subscribers, and in the purchase of paintings towards the formation of a national gallery of modern art. In connection with these latter chances a small percentage of the fund annually subscribed is devoted to the acquisition of modern works of art, towards the formation of a national gallery. This is a feature peculiar to this Association, and it must be gratifying to the members that the Association has a permanent record of its operations in the paintings purchased with this fund, which at present contribute to the enrichment of the Scottish National Gallery. The sums expended in the acquisition of these works of art, and in connection therewith amount to nearly 4,000*l.* The sum at present at the credit of the Gallery Fund is about 500*l.* From the recent exhibition of the Royal Scottish Academy your committee have purchased at a cost of

973*l*. twenty-five paintings and fourteen water-colour drawings. In addition to these works of art, there will be included in the distribution about to take place twelve drawings, commissioned from Mr. George Reid, R.S.A., at the cost of 300*l*. for the purpose of being engraved for the present members. The sixteen engravings illustrative of the scenery of the river Tweed, forming this year's presentation work, have now been completed, and the committee desire to record their high appreciation of the beauty of the drawings, and of the admirable manner in which M. Durand has executed the *facsimile* reproductions. The committee also take this opportunity of tendering to Professor Veitch the acknowledgments of the Association for the interesting and valuable introduction he has so kindly written to the volume, and to Dr. Walter Smith for the original sonnets he has furnished for two of the illustrations. As regards the presentation work for the ensuing year 1885, your committee have resolved that it shall consist of a selection of photogravures or engravings of some of the most characteristic and the best known paintings by Sir William Fettes Douglas, President of the Royal Scottish Academy. Further particulars will be announced in the prospectus for the year.

The committee have considered the letter referred to them at last annual meeting, suggesting that in future winners of prizes should be allowed to select their own pictures. The question raised has since the formation of the Association been from time to time brought up; and the committee, after full consideration, have been unable to come to any other conclusion than that arrived at by their predecessors, that the proposed changes would not be desirable in the interests of the Association.

### ARCHITECTURAL SCHOOL, ROYAL ACADEMY.

THE following students have been admitted into the various classes in the Architectural School of the Royal Academy:—

*Upper School*.—R. D. Fell, Frank Fox, F. Simpson, and J. Thomson.

*Lower School*.—S. Hall, A. B. Mitchell, J. E. Newberry, E. H. Sedding, E. H. Selby, and F. W. Troup.

*Probationers*.—P. Anderson, N. W. Allen, R. S. Ayling, W. H. Boney, W. A. Burr, W. L. Buxton, J. J. Cresswell, F. M. Day, L. Dennis, H. P. B. Downing, H. Druery, L. R. Ford, C. Gill, G. Harvey, T. H. Hitchin, W. H. Howie, H. Hutchins, A. R. Jemmett, A. J. Lancaster, W. Leck, H. C. Manning, F. W. Marks, F. Masey, C. L. Meadway, W. Newton, R. O'B. North, W. R. Schultz, A. Steinthall, A. Sykes, A. S. Taylor, J. B. Thorp, F. J. Webb, and T. G. Wetherell.

### WEIMAR.

A CORRESPONDENT of the *Glasgow Herald* gives the following description of a visit to Weimar, the German town which is associated with the names of Goethe, Schiller, Herder and Wieland:—From the station you stroll down an avenue of limes, at the foot of which, just before you enter the town itself, stands the Museum—a sort of entrance hall to Weimar itself, the home of the Muses. Here you are called on figuratively to put your shoes from off your feet. Unlike most museums, there is not *much* to see here, but what there is well worth looking at. Chiefly to be noted are the mural paintings by Preller. They decorate the walls of the upper hall, and represent the story of the Odyssey. A glance at these will be the fittest prelude to the scenes of classic beauty and pathos which the day will disclose. As we pause before the picture in which the wily hero stands in dusky light by the open grave, and marshals up the spirits of the departed, we feel that our own mission is not unlike his. We stand in Weimar beside the graves of the great dead, and we try to summon up their spirits to tell us how best to guide our life. As we leave the Museum, we bend to the left in the direction of the Palace, which rose in 1790-1803 under the eye of Goethe himself. On the way we pass the statue of Herder, who stands over against the church in which he laboured, with his favourite motto inscribed on an open roll in his hand—"Licht, Liebe, Leben." All travellers are familiar with the interiors of palaces. Windsor, Berlin, Versailles have all the same tale—the same endless suites of reception-rooms, where the rich tapestries and pictures are reflected in the bright inlaid floors below. But with all their magnificence and art-treasures, none of these is so truly beautiful and artistic as the little palace at Weimar. Nor with all their battle-pieces and portraits of princes do any of these suggest thoughts of empire so wide as the little salon here, which, with its furnishings precisely as they were in Goethe's time, seems still to retain the echo of his voice as he used to recite his yet unpublished manuscripts to his kindly court critics. To each of the four illustrious poets of Weimar a room is here dedicated, whose walls are set apart for mural paintings of scenes from their works. Egmont we may remark especially, in the Goethe Room—white and glistening as when he threw off his military cloak and stood in the famous scene before Clarchen's dazzled eyes. Or Faust, as he lies at the end of the Second Part, his soul redeemed

at last by that very yearning and struggle after truth from which it is now delivered, and escaping from the clutch of Mephisto the Destroyer to the Heaven where Gretchen already entreates for it at the Throne of Grace.

As we descend the stair of the Palace we ask the attendant the way to the City Library, which was a frequent resort of Goethe and where still linger many memories of him. On inquiring further whether the aged librarian who knew and remembered the poet is still alive, we are told with a smile that he is, and that he "still makes his little jokes." A few steps bring us there. We are met by the old man himself at the door. He is still fresh and active and fragrant of the past. He knows what we have come for, and leads us at once, almost without a word, into the presence of a colossal head of Goethe in gypsum, cast by the sculptor Von David. It startles the visitor at first. The hair stands back from the great forehead as though the poet had just run his fingers through it and it had not settled back yet. Our guide whispers to us that it had startled Goethe himself when he first saw it, and that he exclaimed "Curios!" The expression seems at the first glance stern and even awful, and we remember how often we have heard the Germans call him "proud," but as we look we see that it is only what is greatest in Goethe—his gigantic personality—looking out from among and unifying the qualities we admire most in lesser men. We are next led round an angle of the library, and find ourselves beside the celebrated marble bust of the poet by Von Trippel which the Germans know as the "Apollo Head." Goethe was 40 years old when he sat for this head, and if he was really like that we do not wonder that Heine, as he tells us himself, on his first interview with the poet, "was nearly speaking Greek to him!" Heine changed his mind, told him instead in plain German that "the Weimar plums were very good," and was relieved to find that Goethe smiled. We, too, shall probably see on a closer look that there is more of the German than of the Greek in the best pictures of the poet. It is with the man as with his writings—classic beauty of form is ever breaking down before the broad strength and geniality of his Teutonic genius. Of the bust before us Goethe himself is reported to have said that he could not see any resemblance to himself in it; but he added characteristically that he had no objections to go down to posterity as so handsome a fellow ("ein so hübscher Bursch"). We may rail at the "realism" of our present day English artists, but the faces of our Carlyles and our Darwins will at least be handed down to posterity as they were in the rugged flesh, and not as they come from the chisel of an idealist. Schiller's head (by Von Dannecker) stands facing Goethe's, but it, too, has suffered. Why should the artist have made the forehead to rise like a cliff to suit any phrenological theory of his own? All such misrepresentation is vain. Schiller's head was exhumed with a view to removal to the ducal mausoleum at Weimar, and identified among seven others that were buried beside it by several independent witnesses, and his forehead retreats! Nevertheless the busts in the library are beautiful works of art, and sufficiently express the men. Schiller sat for the sculptor in 1805, the last year of his life, when death was already on his sunken cheek. Our guide pointed to Goethe, and whispered the word "Glück," then, turning to Schiller, he added "Schmerz." He next led us upstairs to show us his most precious treasure, among a number of toys and gimcracks, to the construction of which departed Grand-Dukes had devoted ingenuity which could find no outlet in politics. We shuddered to think of what our own Peers may some day be reduced to. After a little delay, just sufficient to heighten our expectation, a china cup and saucer were produced in their velvet case, on the side of the former of which is painted, in exquisite miniature, a portrait of Goethe, executed by Sebbers in 1826. The poet is said to have sat thirty-four times for the picture, and if we may judge by the vividness of the likeness, which seems as we look at it through a magnifier to live in the porcelain, we may well believe it. The artist has indeed succeeded in "making a little space beautiful." Like Wagner in Faust with his homunculus, he seems to have caught the principle of life itself and enclosed it in this little cup. As we looked at it our guide was restless and nervous. His uneasiness was only explained when he told us of the narrow escape it had recently made as a visitor was peering at the cup like myself through an eye-glass. The glass dropped heavily from his nose, and unless its faithful guardian had swiftly interposed his hand this "holy grail" would have run a sore risk of passing, like its ancient prototype, into limbo. On leaving the library we took an affectionate farewell of the old man, who presented us with a poem he had written himself on the treasures of the library, and warmly invited us to return.

We had been told by the guide-books that the house in which Goethe had lived, and which is at present occupied by the descendants of his family, was closed against visitors, but we now found that though the rooms themselves were usually closed we might by permission of the housekeeper have free access to the garden behind, in which the poet had passed so much of his time. We crossed a yard and through a court underneath the rooms which (and not any of those which are seen from the public street) were occupied by the poet. The little garden was one mass of lilac, laburnum, honeysuckle, and acacia, intersected by footpaths with their high lines of boxwood. Here we were left fortunately alone to drink in at

our leisure the memories that seemed to float on the scented air around us. The windows of the poet's house look out upon the garden, and as we turned away we were free to pluck a leaf from the old creeper that made its way up to the casement of the poet's own chamber, as it had done fifty years ago when the poet died there calling for "more light."

Within a stone's throw from the house of Goethe is that of Schiller, where the room in which he worked, and the plain deal bed (now heaped high with laurel wreaths) in which he died, his pictures, his old piano, his table, his inkbottles, and what not are freely shown to the visitor. The house has been bought by the Government, and placed under the care of an old lady, whose duty it is to keep it fresh and clean, and to remunerate herself by selling photographs of Weimar itself and its celebrities. We had the opportunity a week later of visiting Thomas Carlyle's house in Cheyne Row, Chelsea, and could not help contrasting its cheerless and neglected appearance with what we had just seen in Weimar. Its doors and shutters are faded and closed, its windows dusty and broken. Truly we are a grateful nation! If we no longer stone our prophets we let our children stone their houses. Gladstone, it may be, and his Government care for none of these things, but is there nobody who does?

As you leave Schiller's house a few steps bring you into view of a statue in the centre of a little square which you at once recognise to be the celebrated "Dichterpaar" executed by Reetschel in 1856. Goethe and Schiller stand here larger than life, each with his hand upon the laurel wreath they hold between them. So skilful the artist that we cannot tell which of the two gives the wreath and which takes it. Although Schiller stands with his head thrown back in an erect attitude which we are told was never his in his later years, and although he was several inches taller than Goethe, he yet does not seem in the statue to get the advantage of it. In the rapt expression of his worn features we seem to read the character of his genius. His fervid, exalted spirit seems hardly to belong to this world. In Goethe's broad, firm face, on the other hand, bent slightly downwards with its sympathy and insight, we seem to see the poet of the many-sided world we live in. Schiller found this life a struggle, and left it early; to Goethe the world had shown itself a home, and he "loved it out of gratitude." Even in their dress we seem to see the difference between the student and the courtier. If the frockcoat and ruffled shirt-front of the older poet suggest that Goethe had something in him of the dandy, what does it matter? Plato was a dandy, and why might not Goethe be? And yet that very coat we saw hanging in a glass-case in the library beside Luther's gown and Bible, and were solemnly assured by the librarian that Goethe could not endure to wear it.

#### SIR JOHN STEELL, R.S.A.

A STATUE of Burns by Sir John Steell, which was commissioned by Mr. J. Gordon Crawford, has been placed in the Embankment Gardens, near Cleopatra's Needle. It was unveiled on Saturday by Lord Rosebery. After the thanks of the assembly had been voted to the donor, the following speeches were delivered by Mr. Faed, R.A., and the Lord-Advocate, on the skill shown by the sculptor:—

Mr. Thomas Faed, R.A., said:—My lords, ladies, and gentlemen—It is unfortunate that we have not amongst us this day the sculptor of this beautiful statue, which Lord Rosebery has just unveiled with an eloquence and feeling worthy of himself and of the great subject he has treated, and I am sure it is as great a misfortune to Sir John Steell as it is to us that he is obliged, through illness, to be absent. If I might mention another misfortune, it would be that I have been selected to bring his honoured name before this great assemblage. I cannot deny that there is a certain fitness in the selection, for I have known him for nearly half a century; but there the fitness stops. We painters are silent workers, and, with a few brilliant exceptions, do not cut a great figure on the platform. The career of Sir John Steell has been a long and honourable one. Before his time, with the exception of Sir John Haining, few men of note in statuary appeared north of the Tweed and remained practising that art. We need not wonder that he has long since gained the honourable distinction of being the father of monumental sculpture in Scotland. It has been his good fortune to have had many opportunities of showing his powers both in his native city, Edinburgh, and elsewhere. In Edinburgh alone we have five or six of his noble works. Of these I may mention some of the best known, naming them in the order of execution. The magnificent equestrian statue of the Duke of Wellington in front of the Register Office; the Queen, over the entrance of the Royal Institution; Sir Walter Scott, enshrined beneath the canopy of Kemp's world-famed monument; and the Scottish national memorial of Prince Albert, perhaps the most honourable of all his achievements, on the uncovering of which he was knighted by Her Majesty. New York holds his Burns and his Scott. Yet, my lords, ladies, and gentlemen, I am sure he will feel as proud at seeing his name carved on the pedestal of Scotland's peasant bard—the world's bard, for was ever man more human?—standing, as it does, on the margin of England's mightiest and most historic

river, as of any honour hitherto bestowed. Let us hope that Macaulay's prophetic New Zealander may meet with someone to point out to him Steell's statue of Burns, or at least the place where it stood. I am sure that you will join with me in wishing that the man whose appreciative brain and cunning hand conceived and carved this beautiful statue may have a renewal of health and vigour, and that he may be called to execute a companion to the one we have unveiled this day.

The Lord Advocate said:—In the inability of Sir John Steell to be present, I have been asked on his behalf to acknowledge the graceful and eloquent tribute which was paid to his qualities by Mr. Faed. To all who hail from the north Sir John Steell's name has long been a household word. I doubt whether there is anyone here old enough to recollect the time when he was not in the forefront of our modern sculptors. Somewhere about forty-five years ago he was appointed Her Majesty's Sculptor for Scotland, and during the whole of that time it has been a pleasure to all of us to observe his works. Mr. Faed has recalled that group, or rather that succession of great works, that meet us whenever we take our walks abroad in Edinburgh. If anyone is disposed to walk along that noblest street in the world—Princes' Street of Edinburgh—and if he chooses to begin at the east end, the first object which will rivet his gaze will be that equestrian statue, full of life, and vigour, and spirit, which stands so proudly before the Register Office. We know that at no great distance from the place where we are now assembled the image of the illustrious Duke has recently descended from its lofty pedestal and vanished from view. But so long as artistic taste and the admiration for warlike valour remains, Sir John Steell's statue will ever endure. When we proceed a little further west we find the seated image of Sir Walter Scott looking thoughtfully and gravely down upon us. Then Her Majesty meets us at the Royal Institution; and if we turn northwards into George Street, we find one of our greatest and most respected divines, Dr. Chalmers. It was but a fitting climax to that series of great works that it should be the privilege, as it was the pride, of Her Majesty's sculptor to execute that memorial which adorns Charlotte Square. I dare say to those of us who have the duty of passing a good deal of time in London it must be a deprivation not to find around any great works to which we were accustomed. Hence we must have a feeling that there has been filled to day a great blank in the placing of that magnificent statue in one of the finest promenades of this the proudest capital of the world. I dare say Burns, who never was here himself, may feel rather solitary seated there alone, but Mr. Faed has very well indicated a way in which that drawback of solitude may be removed. I do not see why some other replica of Sir John Steell's work should not be gifted to this great metropolis by some other generous donor—say of Sir Walter Scott. It would be an additional pride to every Scotsman in the metropolis, as well as a benefit and a pleasure to the friends amongst whom we live. I can only say I am sure this will be one of the proudest days of Sir John Steell's long and honoured life, and that he will never forget the tribute that has been paid to him by your presence here to-day.

#### BUILDERS' BENEVOLENT INSTITUTION.

THE thirty-seventh annual meeting of this institution was held at Willis's Rooms on Monday, Mr. George Plucknett, J.P., in the chair. The annual report read by the secretary, Major Brutton, stated that during the past year seven pensioners (six men and one woman) have died, and nine new ones have been elected (seven men and two women), making an addition of four pensioners. Two widows of deceased pensioners have also been admitted to the benefits of the institution. There are now fifty-eight pensioners on the funds of the institution, and the committee earnestly appeal for increased help. They acknowledged that very valuable aid was given by the president for the past year, Mr. Henry G. Smith, and by the gentlemen who superintended the arrangements for the annual dinner and ball. In conclusion, the committee express their satisfaction in announcing that Mr. Stanley George Bird had intimated his willingness to become president for the ensuing year, and that the annual dinner will take place at the Freemasons' Tavern on November 6. The balance-sheet showed the total receipts from all sources to have been 5,266*l.* 2*s.* 9*d.*, while the expenditure was 2,273*l.* 10*s.* 5*d.*, leaving a balance in hand amounting to 2,992*l.* 12*s.* 4*d.* The report and balance-sheet were adopted on the motion of the chairman, seconded by Mr. Bussell. Votes of thanks to the trustees, auditors, and committee having been carried, Mr. Stanley George Bird was, on the motion of the chairman, seconded by Mr. Thomas Stirling, elected president for the ensuing year.

A Museum of Casts is to be founded in Vienna. M. Lützow has been appointed director. A collection of subjects will be obtained from the galleries of the British Museum, the Louvre, the Trocadero, &c. It is intended to make the new museum of a comprehensive character.

## NOTES AND COMMENTS.

ONE of the three great *ateliers* which are connected with the Ecole des Beaux-Arts in Paris, has been directed by M. HÉBERT. In 1839 M. HÉBERT arrived in Rome, having won the Grand Prix in painting, and in course of time he was appointed director of the school in the Villa Medici, in succession to M. ROBERT-FLEURY, who held the office for less than the customary period. It has been arranged that M. HÉBERT is again to undertake the directorship, which has been lately filled by M. CABAT, an artist whose works were rewarded with a second-class medal fifty years ago. It will be necessary to appoint a successor in the Paris *atelier*, and it is understood that the choice lies between M. BONNAT, the portrait painter, and M. BOUGUEREAU. The best known paintings of M. HÉBERT are those which represent scenes in Italian life. He was the first to depart from the conventional prettiness which was sanctioned by such men as EASTLAKE and UNWINS in England. His realism was one of the influences to which the modern school of France owes its existence.

It has been decided by a majority of the Court of Common Council that the suggestion of the Select Committee of the House of Commons on Thames Communication should be adopted. The Committee reported in favour of the construction at Little Tower Hill of a low-level bridge with two openings, each about 100 feet span, and crossed by a pivot swing bridge, and on those lines the Council intend to work. A design is to be obtained by the Bridge House Committee, who have power to seek the assistance of other engineers besides the Corporation officials, and if approved, a Bill will be lodged in November seeking powers to carry out the work. The principal opponents to the scheme are the wharfingers and owners of riverside property between the Tower and London Bridge, who maintain that the bridge will do much towards completing the ruin of London as a port. But prophecies of the kind are the accompaniments of all useful undertakings. The influence of the bridge in enhancing the value of property in the neighbourhood of the approaches appears to have been overlooked in the discussion.

It is proposed to obtain an additional source from which to derive the supply of water from Paris. The site, which has been selected by M. BELGRAND, is on the plateau of Morvan, in Basse Bourgogne. The quantity to be taken may amount to 150,000 cube mètres in twenty hours, for which a rent of seven centimes is to be paid. If a larger quantity is taken, the price for the excess is to be reduced to three centimes. At the present time water is freely used in cleansing and allaying the dust in the streets of Paris, and has been for some months past. The expenditure almost seems to be extravagant in the eyes of an English town councillor. There seems to be no stint of water for fountains, baths, and the like. When the new source becomes available, the Municipal Council of Paris can afford to be even more liberal with water than they are now.

SCOTTISH painters have no reason to complain of modern patronage. According to a statement which was made at the meeting of the Northern Art Union, it appears that in 1828 the sales of pictures from the exhibition of the Royal Scottish Academy did not amount to more than 35 guineas, and as the Dean of Faculty expended 30 guineas, the whole of the remaining purchases amounted to five guineas. It needed no small amount of enthusiasm to follow art as a profession in those days.

A COMMITTEE has been formed, with Sir JOHN LUBBOCK as treasurer, in order to prevent the destruction of valuable monuments of antiquity when found in London and its vicinity, or, when such destruction is inevitable, to secure the execution of proper plans and drawings. The necessity of an organisation for this purpose is just now made evident by discoveries of considerable interest progressing in Bevis Marks. In the course of excavations at the corner of Castle Street, foundations have been disclosed which evidently belonged to a structure of great solidity and strength. A preliminary examination showed the remains to be composed of large fragments of Roman sculpture, taken from some anterior building in the locality, and used as building materials. By the courtesy of the contractors, Messrs. MOWLEM, BURT & Co., some of these pieces

were extracted. These were of the highest interest; but as the works could not be delayed an hour, they would have had to be covered in and again buried, if it had not happened that Mr. PRICE, the secretary of the London and Middlesex Archaeological Society, undertook the risk and cost involved. With the sanction of Colonel HAYWOOD, City Engineer, further excavations were accordingly commenced, from which interesting results have been obtained, and the work will be continued until everything of importance has been removed. In the meanwhile, arrangements will be made for the safe custody of the objects found in one of the public museums. To meet this and future emergencies a fund is being raised to be administered under the supervision of the General Committee by a small executive committee.

THE trustees of the Earl of CRAVEN have decided that during his lordship's minority there are to be no explorations at Woolstone, in Berkshire. This will be a great disappointment to archæologists. The discoveries of Roman remains, which were made without difficulty, were enough to excite the imagination, and it was supposed that a second Silchester was not an improbability. One archæologist says that at a distance of about thirty yards from the Roman Villa, he uncovered another pavement, somewhat mutilated, the tessellæ larger than those previously found, and laid in the well-known key pattern; in the centre and level with the pavement was a stone about a foot square, perforated, which upon being raised was seen to have rested upon two others placed perpendicularly, thus forming a small cyst. From the remains therein found it was evidently the burial-place of a child; it had, however, been previously opened, the perforated stone being broken in two places. In walking through the various fields, fragments of Roman tiles, tessellæ, and pottery are found in large quantities, and the ploughshare turns up the foundations and portions of walls of stone. For nearly a mile in extent these traces of early habitations are to be met with every few yards, giving evidence of a settlement of considerable size. The tessellated Roman pavement recently discovered at Woolstone has been given to the Ashmolean Museum, Oxford, by Lady CRAVEN.

THE risk that is incurred by architects and engineers in dealing with sub-contractors, was exemplified by a case which was heard last week at the Suffolk Assizes. The circumstances were as follows:—A contract had been entered into by Messrs. PEARSON in 1879 for the construction of the Ipswich Sewerage Works, but it did not include penstocks and other ironwork. Afterwards Mr. BRUFF, the engineer, agreed that the contractors were to supply the ironwork. They naturally wished to obtain the articles from the stock of some London house. The engineer recommended that the order should be given instead to a local ironworks owned by Mr. MUMFORD. There was, however, no evidence of any order in writing from Messrs. PEARSON. The prices were settled by Mr. BRUFF, and the invoices for the ironwork supplied from time to time were made out in his name. Mr. BRUFF said that he included the amounts for the ironwork in Messrs. PEARSON'S certificates; but, on the other hand, one of the contractors said that the ironwork was not included in their monthly accounts, and they had nothing to do with the ordering of it. The balance unpaid amounted to 447/. The case was heard before Mr. Justice DENMAN alone, and under the circumstances it is not surprising that his lordship wished for the assistance of a jury. The judge was of opinion that Mr. BRUFF acted as the agent of the contractors—a position which was not to be desired or encouraged. If the invoices were interpreted literally, then Mr. BRUFF was the debtor. Accordingly, after pointing out the unwisdom of the arrangements, judgment was given for the sum claimed. It may be assumed that if the action had been taken against the engineer, judgment must have gone against him.

THE National Association of Master Builders of Great Britain held their 13th half-yearly meeting at the rooms of the Central Association of Master Builders of London, on Tuesday, July 29, Mr. STANLEY G. BIRD, the President, in the chair. The meeting was largely attended by representatives from the provincial and local Associations. After the routine business had been disposed of, several matters affecting the trade were discussed, more particularly the question of quantities. The next meeting will be held at Lincoln.

## ILLUSTRATIONS.

## DESIGN FOR THE WAR OFFICE AND ADMIRALTY.

WE publish this week reductions of two of the geometrical drawings which represent the design by Messrs. GLOVER & SALTER for the new offices for the Admiralty and War Departments. It is one of the nine designs selected by the judges, and is the only one which is Gothic in style. From the small scale of the illustration justice is hardly done to the detail of the original, but we intend to publish a bay on a larger scale.

## HOUSE AT KILLINEY, CO. DUBLIN.

## HOUSE AT WHALLEY.

THIS house, which belongs to Mr. J. N. WITHERS, is one of a number of houses built in Whalley during the last eighteen months from the designs of Messrs. STONES & GRADWELL, architects, of Blackburn. The walls are faced with pressed bricks from Coppull, near Wigan; and the quoins and moulded base, string and label courses, the moulded angles to windows and doors, and the patera in the gablet at front, and also the ridge and hip tiling, are all from the works of Mr. J. C. EDWARDS, of Ruabon, and, being of a dark-red colour, contrast agreeably with the lighter colour of the main walling. The only stone used is for window-sills, door-steps, and thresholds, and is from Longridge, near Preston. The roofs are covered with green Velinelli slates, except the porch roof, which is tiled. The woodwork throughout is yellow pine, painted. The lead lights in the vestibule and porch, and in the staircase window, have been tastefully executed by Mr. JAS. JONES, of Charles Street, Manchester. There is a very fine view from the balcony on side elevation over the Ribble Valley, and from the front windows over the picturesque village of Whalley to Whalley Nab, so often mentioned in HARRISON AINSWORTH'S "Lancashire Witches."

## MISSION CHURCH.

THIS mission-room is proposed to be erected upon the site of a large church to be built afterwards. When the church is built the mission-room will be incorporated into the scheme, and be used as school and parish-room. The cost is 400*l.*, exclusive of seats, pulpit, &c. The walls are hollow, built of red brick; internally they are plastered, and have wood dado. The roof is covered with plain red Staffordshire tiles. The architects are Messrs. CLARK & MOSCROP, Feethams, Darlington.

## RESIDENCE, VESPER GATE, KIRKSTALL.

THIS house, which was completed during the summer of last year for Mr. EDMUND BUTLER, is situated near the celebrated Abbey, and from the windows of the principal rooms charming views of the ruins are to be obtained. The building may be described as a residence in miniature, it being the owner's wish that the design should have a cottage-like appearance. It is built of deep red brickwork, with red terracotta strings and labels, the gable ends, some of them, being tile-hung and others corbelled out and timber-framed with panels, cemented and finished a cream-white colour, and provided with overhanging barge boards with shaped moulded pendants. The roof is covered with Staffordshire red tiles. The exterior woodwork is painted a peacock blue-grey colour, the window casements being ivory white, the former tint contrasting well with the deep red of the brickwork. The interior contains three reception-rooms, hall, gent's coat-room, butler's pantry, kitchen and scullery, six bedrooms, dressing-room, linen-room, bath-room, and other requisite accommodation, besides good cellarage in the basement. The chimney-pieces and other internal fittings were all specially designed by the architect. The total cost, including outbuildings and entrance gates, was a little over 1,300*l.* The work has been carried out from the designs and under the superintendence of Mr. WILLIAM H. THORP, A.R.I.B.A., of St. Andrew's Chambers, Park Row, Leeds.

## SHERE CHURCH, SURREY.

THE illustration is taken from a water-colour drawing by Mr. E. F. C. CLARKE, architect, which was admired when exhibited at the Dudley Gallery.

## TOWN HALL AT REVAL.

RUSSIAN buildings in the smaller towns are disappointing on close inspection, though effective enough when grouped and at a distance. The old town of Reval—as distinct from the new suburbs—is built and fortified with enceinte and moat on a hill overlooking the harbour. The town hall illustrated dates from the eighteenth century, the interior showing good detail and character; but the long period of snow necessitates the monotonous plastering of all exterior work, although well built with the stone of the district. In the summer the town looks gay with parti-coloured distemper, but winter gives it a smudgy look. In the churches and public buildings were more elaborate work, but the cold on the one hand and the omnipresent gendarme or soldier on the other, makes sketching and note-taking rather risky work in these Nihilistic times.

## HOUSE AT DELFHAVEN.

THE quiet and characteristic town of Delfhaven on the Maas has many houses of the date of the architectural importance of the one chosen to illustrate. The majority have flush windows with and without architraves; the house sketched showed reveals. The bricks are good in colour, and measure 8½ by 2 by 4 inches; they are finely axed and cut. The shop front appears to be an alteration on the original design, though about of the same date, its detail being quiet and good. The set-off showing the diminished thickness of the wall on the upper storeys is very effective, and might be more often used in modern work with good results. The whole is executed with care and completeness, though simple in detail.

## TOWER OF BETTWS CHURCH, MONTGOMERYSHIRE.

THIS is a type of church tower not uncommon in the county of Montgomery. That at Newtown is very similar. The merit of the design is the picturesque manner in which the tower is terminated, and the skilful combination of bell staging and roof framing. Nothing could be happier than the simple method here adopted, of bringing a considerable breadth of wall into a pyramidal form within a moderate height, and at the same time yielding in the whole form a proportion in every way satisfactory. The contrast between the close timber framing of the upper stages with the frequent repetition of deep shadow produced by the intermediate spaces, and the breadth of plain surface in the lower part, is a master-stroke of design. The illustration is a reproduction of drawings by Mr. J. H. BECKETT, of Mr. LYNAM'S office, Stoke-on-Trent.

## THE ADMIRALTY AND WAR OFFICE COMPETITION.

THE judges appointed to consider the designs in the competition for the new offices for the Admiralty and War Departments, on the site adjoining the north side of the Horse Guards, have agreed to the following report:—

1. The competition consisted of two parts, the first an open one of sketch designs, subject to the conditions laid down in the instructions issued in September 1883, by the Commissioners of Her Majesty's Works and Public Buildings.

The judges were directed to select ten designs from those sent in to this first competition, or such less number as they might think fit, the authors of which were to be invited to compete in the second or final competition, for which matured drawings were to be submitted.

2. One hundred and twenty-eight designs were sent in by March 1 of this year for the first competition, the names of their authors being contained in sealed envelopes, which were not opened until after the selection. The judges, after full consideration, selected nine designs, the authors of which were invited to enter into the second competition, for which further instructions and suggestions were issued.

The authors of the selected designs are as follows:—Messrs. Glover & Salter, Poultry, London; Messrs. H. Hall & W. H. Powell, Doughty Street, London; Messrs. Leeming & Leeming, Halifax; Messrs. Maxwell & Tuke, Manchester; Mr. Thomas Porter, Norwood; Messrs. Spalding & Auld, Queen Victoria Street, London; Messrs. Stark & Lindsay, Glasgow; Messrs.

Verity & Hunt, Regent Street, London; Messrs. A. Webb & E. J. Bell, Queen Anne's Gate, London.

3. The matured drawings of the second competition were sent in by June 21 last.

4. The judges, after a careful examination of these designs, selected three as possessing especial merit, namely, those of Messrs. Leeming & Leeming, Halifax; Verity & Hunt, Regent Street, London; Messrs. A. Webb & E. J. Bell, Queen Anne's Gate, London.

5. After further consideration of the relative merits of these three designs, the judges are unanimously of opinion that, taking the plans and elevation together, and having regard to the conditions of the competition, Messrs. Leeming & Leeming have produced the best design, and they accordingly recommend to Her Majesty's Government that, subject to the approval of Parliament, Messrs. Leeming & Leeming be employed as architects of the new building for the Admiralty and War Office.

### SANITARY ASPECTS OF INTERNAL FITTINGS, &C.\*

BY G. AITCHISON, A.R.A.

THE two prime necessities for health are pure air and pure water. I believe we in London have generally little to complain of as regards the quality of the water supplied us by the companies, however much we may complain of the cost; but as to the air, "the least said is the soonest mended." Swift's description of London milk in his day pictured a wholesome beverage as compared with the air we have to breathe. I presume the native air of London is much the same as other air, perhaps a little moister from the river, but we necessarily adulterate it by the breath and exhalations of 5,000,000 human beings, without taking into account the breath and exhalations of millions of horses, jackasses, dogs, cats, mice, rats, pigeons, sparrows, and other animals; we wilfully adulterate it by the beastly condition of our roads and streets, by pouring into it the vapour from our sewers, and from the blow-holes of the Metropolitan Railway, and the gas and smoke from our factory, steam-engine and domestic chimneys, so that what with the carbonic acid gas, the sulphuretted and carburetted hydrogen, carbonic oxide, the vapours of diluted sulphuric, nitric, and muriatic acids, our constitutions are ruined. But there are thousands of other noxious vapours that help to form the delicious fluid we breathe; and, lest the gases and vapours should not supply us with enough poison, we have the mixture thickened with the fine particles of iron, stone, leather, cotton, wool and hair, horse-dung and soot. Those who have gone before me have probably told you some of the requirements for keeping the air and water inside your houses no worse than they are outside, for if you want the water better, or at least more wholesome, you must boil and then filter it through a clean filter; you must sift out the coarse particles from the air, filter or burn the fine particles, and absorb the deleterious ingredients. You have probably been told how to keep your houses dry, how to prevent damp vapours from rising inside them, how to let in enough sunshine, and how to warm and ventilate them; and, as the learned gentleman who comes after me will tell you how health is affected by colours, there is little enough left for me to say.

The old Roman's prayer was to have a sound mind in a sound body, and, were it not for the foul air of London, there seems little reason why Londoners should not be as strong and healthy as the old Romans, if they would but imitate their example; for, though we have less warmth and sunshine, we are rarely afflicted with ague, and have none of those mephitic exhalations which are supposed to cause their pernicious fever. The Romans lived hardly and sparsely, drank but little wine, and well tempered that with water; they exercised themselves every day in gymnastic exercises and their drill; they rose before the lark, and went to bed with the lamb, and by means of a daily Turkish bath kept their skins in perfect condition.

You all know that Count Cornaro was so eaten up by indigestion, gout, and rheumatism, that when he was forty he was told by the doctors he had not six months to live, yet, by merely limiting his diet and his drink to what was purely necessary, though he was no teetotaler, taking plenty of outdoor exercise, and keeping himself cheerful, he lived in health and happiness until he was ninety-eight years old, and some say that he was more than a

hundred. There is another point to be mentioned. Don't over-work yourselves; remember the French proverb that you should "Never kill yourself to get your living." And don't fret yourselves, "Sufficient for the day is the evil thereof."

I fear you will say all this has little to do with the internal fittings and decorations of houses, and that is true enough; but if your bodies are crazy with late hours, over-work, over-eating, over-drinking, want of exercise, want of rest, and want of quiet, you would find Paradise itself unwholesome. I am inclined to believe, in the present state of London air, that if every house could be properly built and properly ventilated, it should be hermetically sealed to the outer air; but I fear such perfection is hardly to be looked for in our time, and I therefore say that the things we have mainly to guard against are dirt, dust, and the fouling of the air. By dirt, I mean, when speaking to an audience like the present, the street mud we bring in with us, consolidated external and internal soot and dust, and such soft matters that are occasionally dropped about, such as particles of food, and the like. Every crack in a floor gets filled with this, so it is of the utmost importance that this dirt, if not to be excluded, should at least not rest for ever with us, and be liable to putrefy when exposed to damp and warmth. Every open joint between the floor-boards, and beneath the skirting, is usually filled up flush with dirt. Besides the dust from the streets, we make our own dust inside our houses; particles from shoes, from wood and stone, from our clothes, oil-cloth, mats and carpets, are constantly being worn off and carried for a time in the air, together with the scales of our constantly renewing skin; and as soon as the moving air is overlaid or becomes comparatively still, everything is covered with light dust, and a great deal of this dust is what the doctors call septic, or putrefying dust. Mr. Brudenell Carter, the eminent oculist, in his letter to the *Times*, described how he had reduced this to a small amount, and that, in consequence, the health of his family had improved. As regards floors, constant wetting is not wholesome, and even scrubbing will not remove dirt far down in the crevices of boards. Nothing is better for preventing the permanent location of dirt than really good hard wood polished parquet, but if that be found too expensive, then let the joints of the boards be well scraped out, filleted with wood when wide, and let all the joints be puttied. And let the whole floor be painted or varnished; dust is then more easily and completely swept up, and a wet flannel cleans the floor; but with parquet, perhaps a washing once a year is enough with clean sweeping, and the wholesome application of turpentine and beeswax.

These remarks apply also to all open joints in woodwork, furniture and plastering; they all get filled with dust, and should be puttied up, and the dust kept out. Smoothness of surface is also a great help to cleanliness, and certainly as few ledges and holes for dust as possible should be left where the parts cannot be daily dusted. This particularly refers to wall surfaces and to undercut ornaments in cornices and the like; tall bookcases and cabinets always have their tops covered with thick dust.

As to woven things, whether of cotton, wool, or silk, the less there are of these about a room the better; and wholly carpeted bedrooms are simply an abomination. A few rugs in sitting-rooms for the feet are certainly all we require, and woollen shoes are better than rugs in a bedroom, for, though rugs are easily moved and swept under, we know from Mr. Spurgeon's converted housemaid that this is not always done, for when she was pressed as to her works that were to prove her faith, she triumphantly pointed out that she now never swept the dust under the mats or hearthrugs, but always carried it away.

What is still worse than a carpet, which is usually beaten yearly, is tapestry or other woven hangings, which often remain in position until they are worn out. Blinds we must have, but they can be glazed, and they generally get a yearly washing; but we might altogether abolish door and window curtains, and woven mantel-shelf coverings and such like follies. It would also be healthier if we covered our chairs, seats and sofas with leather, instead of silk, velvet or cotton. The gilt and enamelled leather we can get, if not quite so beautiful in point of sheen, may be of excellent design and harmonious colour.

Next to polished wood, tiles, marble, glass and marble mosaic, the best wall finish is oil paint; this can be made agreeable to the eye by simple flat tints of harmonious colour, or it can be ornamented with floral or arabesque ornament, or with the highest triumphs of the painter's art, and this last will not only mark the owner's real taste for art, but will prevent the accumulation of dust on the picture frames.

Unfortunately oil paint, except in flat tints, is beyond the reach of all purses. We must all admire the great skill that has been displayed in the designs of paper-hangings, which charm us by the beauty of the forms and colours with which they are enriched. It is needless to say that if damp gets into the walls or partitions on which paper is hung, it at once becomes a source of danger from the putrefaction of the paste with which it is hung, and the size used in its printing. Wall papers too absorb foulness from the atmosphere, and must be often renewed, and when this is done, it is of the utmost importance that all the underlying paper should be stripped off and the walls washed.

Flock papers should never be used, except when they are

\* A paper read at the Conference of Architects at the International Health Exhibition.

painted over, as they form a natural receptacle for dust, and seem to absorb the greatest quantity of foulness from the air, and when the flock is not dyed "in-grain," whenever they are touched some of the colouring matter comes off and is mixed with the air of the room.

I am greatly inclined to recommend the varnishing of all papers, they can then be cleaned with a sponge; but it is absolutely essential to varnish them in nurseries. Children will lick the papers, and neither lead, copper, nor arsenic can be good for them, and neither size nor whitening are substances you would give to children without medical advice.

Let me say here that you cannot have your windows cleaned too often. When they are dirty they not only exclude light and sunshine, but are covered with thickened human exhalations and dust. If you are wealthy enough to have a dressing-room, banish into it every superfluous article from the bedroom; half the bedrooms in London are encumbered with cupboards full of boots, and wardrobes of old clothes, with baskets for dirty linen, books, ornaments, curtains, carpets, and the like, not to speak of mouldy sponges, nail and tooth-brushes; these things occupy some of the air space, and pollute the remaining air with their exhalations.

By far the most important thing in a room is its ventilation, yet as a rule no room has any direct ventilation, except through the chimney and an open window, and when the window is shut the only ventilation is by the fireplace, so that all the air that comes in is tainted by the soot; the highest point of the opening is below the mouth when sitting, and often when in bed. If anyone wants to know the effect of this, let him get the library ladder, and go gradually up it when he has been sitting long in a room with the door and window shut and a gas-light burning; a foot or two above the level of the burner the air is found to be much hotter and closer, very much more so when he is above the top of the door, and unbearable above the top of the window, for some air generally gets in from their crevices, particularly when the room is much warmer than the air in the passages or the street.

It is stated that to keep a closed room sweet, fifty cubic feet of air is wanted for each person for every minute he remains in it, or three thousand cubic feet for an hour. Consequently a room, 20 by 15 by 10 feet high, only contains enough wholesome air for one person to breathe for an hour; most of us would consider this a large bedroom, which we should be content to occupy without any express ventilation for from eight to ten hours. Fortunately for us we raise the temperature of the air of a room by merely remaining in it, and the colder air then seeks an entry. The imperfection of workmanship affords access to the fresh air through the crevices of ill-fitting windows, doors, floorboards, skirtings, and the like, besides what penetrates through the substance of the walls, partitions, and ceilings. Were it not for this accidental fresh air death from suffocation would be quite common in bedrooms without a fireplace, *i.e.* if the rooms were as hermetically sealed as the receiver of an air pump. But we may see what damage we are doing ourselves, when we know that one of the main exciting causes of consumption is foul air. In this dark climate artificial light must be used in our sitting-rooms, and is generally used in our bedrooms. For an equal illumination gas fogs the air less than any other light got by combustion, and the reason we feel gas more is because we use much less light when we burn lamps and candles, and also because it is rarely perfectly burnt, and some escapes into the room; gas must have some sulphur left in it to insure detection when it escapes. At any rate we all know that a room well lit by gas will communicate its foul taste to the air in ten minutes after it is lit.

I have found that a room may be fairly ventilated, and be free from the taste of gas by using Boyd's hygiastic grates, which supply fresh outside air warmed in a chamber at the back, with Rickett's or Hammond's ventilating gas pendants, which not only carry off the products of combustion, but also remove much of the vitiated air from the room. In new houses the ventilating-box of the gas burner should be carried into a hollow chamber round the flue pipes, or into one of Boyd's ventilating flues; these are made of iron plates forming the withe between the smoke flue, so that when there is a fire the ventilating flue is heated.

When this ventilating box is carried into a smoke flue, or even into an empty flue, particularly when ventilating grates are not used, there is often a difficulty with it; in the case of smoke flues the smoke is brought into the room, and in case of empty flues the cold air is often drawn down so violently as to extinguish the gas; or when the draught is less to cause the gas to flicker, so that you cannot read by it. We may hope soon to have in our rooms the electric light in use; but even then it will not enable us to dispense with ventilation.

It has been found that the colours of rooms have a very important influence on health, but this subject will be treated by my successor.

I have no doubt that beauty of form and colour have a very important effect upon our health. Nature makes everything useful, and most things beautiful; and as she usually attains many ends by one means, the beauty she so lavishly spreads for us may be as good for our health as it is necessary for our delight. All of us can bear witness to the dulness of a room of one colour, in which we have to sit when we are without occupation, and the desire we

then have for some beautiful and intricate pattern to relieve its monotony. Lord Brougham's well-worn quotation then impresses us:—

The want of occupation is not rest,  
A mind quite vacant is a mind distress'd.

When a room is adorned with pictures we have not merely occupation, but delight, and those higher emotions that are only excited by the fine arts. When we choose wall papers those that are more beautiful in form and colour are to be preferred. We should, however, satisfy ourselves that the patterns on the papers with which our rooms are hung have not a look of motion. Nothing is more distressing than to be in a room where the pattern of the paper seems always crawling like a bag of worms. It would be well if we could have all things about us beautiful in form, elegantly simple, and all the colours harmonious and restrained; these great qualities seem to impart to us the feelings of self-restraint, dignity, and repose.

I am afraid I have trespassed too long on your attention, and I can only hope that the few simple truths I have put before you in so homely a manner may have the effect of drawing your attention to this subject; and if this paper does no more, it may serve as a contrast to the learned and eloquent papers that have gone before, and will follow it.

## HYGIENIC VALUE OF COLOUR IN THE DWELLING.\*

BY WILLIAM WHITE, F.S.A.

IN treating of this subject I must claim your attention briefly to the hygienic value of colour in itself, and apart from the pigment or colouring matter which represents the colour, and with which alone we are commonly considered to be primarily concerned. Colour has been regarded too much as a mere matter of taste, art, fashion, fancy, luxury, civilisation. It is all this, but it is a very great deal more than this from a sanitary point of view. To some it may seem trifling, to some a mere truism, when I gravely and seriously maintain the great need there is for teaching the public generally that colour is indispensable to man's well-being and happiness; and that the deprivation of colour might render him liable to physical and even mental deterioration.

Good colour imparts to the interior of a dwelling a finished and cheerful effect, to which none can be wholly insensible whatever may be their notions as to its real influence. Our optic nerve is directly and actively exercised by the presence of colour. The senses are thus affected by colour as they are by other external influences, such as light or warmth. It is a recognised pathological fact that colour of some sort is indispensable to the healthy condition of the eye, and that the condition of the brain again is greatly dependent upon the healthy action of the nerves thus affected. These nerves are affected in a way sensibly different by different colours; in other words, in obedience to, and in accordance with, the pace at which the pulsations of light reach the eye, and upon which depends the nature of the colour seen. This sensitiveness extends also to the brute creation. By red these nerves are excited. By green, in like manner, they may be soothed; or they may be rendered torpid by the presence of blue. Yellow, like light, is the colour which the most strongly attracts the eye to itself. We are affected by black and white in the same sort of way as by darkness and light. Light in moderation will produce alertness or wakefulness; in excess it may produce restlessness and languor by weakening or dissipating the powers of attention. Shade may induce a frame of mind favourable to attention, contemplation and repose; in excess it may induce melancholy and depression.

It is undeniable that the human system is thus affected; and when, from want of proper colour, these nerves have not been duly exercised, red is the colour most acceptable to the eye, bringing into healthy action the organs that had become inert. Hence, again, it is, that after long and close application, especially within doors, the eye can repose with satisfaction upon the soft blue of the sky or of distant scenery. The change is really needed; by the colour alone the optical sense is relieved, and the eye is content to rest, in its extended focus, upon this cool and refreshing and, as it were, more distant colour—this perfect mixture of black with white, of darkness with light. It may be of comparatively small moment to those who enjoy constant change of scene, occupation or action. But all who labour require recreation and refreshment. And it is surely difficult to understand how it is, that with all the popular outcry for light and cheerfulness in hospitals, unions, schools, homes for the poor, a similar outcry for even a moderate amount of well-disposed colour has been but rarely if ever heard. That the sick and the poor should necessarily be condemned to drag out their existence within whitened walls, and without a spot of colour to relieve the dulness, to cheat

\* A paper read at the Conference of Architects at the International Health Exhibition.

the cheerlessness of their monotonous life, shows that sanitation has not made the same advance in this as in other branches of the science. And herein Miss Florence Nightingale has much to answer for. In her excellent and popular notes on Nurses and Hospitals, she recommended the use of glazed pure white tiles for the lining of the wards, to the exclusion of buff and red, or other colours which might be more cheerful, less glaring, and less costly.

Colour may be called a plaything or luxury, but there are few persons, if any, who would be able to live for a long period in a light whitewashed, or in a dark blackwashed, apartment, void of other colour, without deterioration. In the one case a tendency to idiocy might be induced, and to melancholy madness in the other. People have been blinded by the white glare of the desert sand, or of the mountain snow. They have become mad or imbecile through confinement in a dark cell. This must not be called an exaggerated illustration, dragged in as a mere sensational argument; for as in other matters, it is mainly through the more fatal results that men can be brought to see the great danger of neglecting precautions which to them have appeared to be trifling, needless, and obscure. I have learnt, by my own experiment, that in the blinding, burning snow of high altitudes the eyes and the skin may be effectually protected by a change apparently so very slight and trifling as that of wearing a brown gauze veil instead of a blue one. Special colours have been used medically in shades and glasses for the protection or preservation of the sight. The fact of some blind persons being able to feel colour with the finger shows how wonderfully their perception is connected with the whole nervous system. I remember the case of a blind boy who described the touch of a scarlet geranium as the sound of a trumpet. It is said that many of those who are called colour-blind are not insensible to the influence of colour, although they may not have the power of distinguishing between certain complementary colours. The optic nerve may perform its office, but there would seem to be some local condition of the retina or of the cornea which interferes with the reception of certain rays.

In order to be healthy and cheerful, colour should be æsthetical; that is, in true accord with right perceptive feeling; in accord with Nature, from the study of which all our best colouring is derived. We need not, for daily use, gaudy and startling effects, nor yet a dull monotony, but colouring of such force and variety as shall be essentially cheerful and agreeable. Hence we see that the employment of colour is not a matter of mere option or of taste, but of healthful, cheerful, and wise enjoyment. It must not be said, therefore, that I unduly exalt the office of the house decorator if I insist upon the artistic employment of good and harmonious colour, as well as upon the use of wholesome colouring matter in the most ordinary finish of the dwelling. And this brings us to the practical application of the subject to common use.

It is of course imperative that the walls should be constructed, and prepared, properly to receive decorative finishings. The necessity for this yet more strongly forces itself upon our notice when we find that the elements of decay supposed to arise from damp in blistered softening plaster are intimately and unmistakably connected with bacterian life and activity. The investigations of M. Parize have shown that this life will permeate from an infected surface into those portions of a wall which may appear as yet to be perfectly sound. This may serve to indicate also the unwholesomeness of accumulating layers of old paper-hangings, and bad paste or size.

The preservative properties of preparations of lead and arsenic, when employed in decorative work, whether internal or external, arise no doubt to a considerable extent from their antagonism, as to all organic life, so also especially to this species of vitality. But this cannot justify the continued unwholesome use of lead and arsenic for the decoration of dwelling-rooms, though the house-painter will still insist that white-lead and oil-paint form the most efficacious covering medium that has been discovered. The trade in it has been long established, and he has been educated in its use; he is disinclined to change, and he justly hates mere experiment. But in interior painting substances are now gradually taking the place of white lead, which have ceased to be open to the charge of being experimental. The scientific investigation of their respective merits can be carried on only by those who devote themselves for the time to the subject, and many of these things will be submitted to scientific test under the auspices of this exhibition. But the substance called Charlton-white seems to have established its reputation as a wholesome and permanent covering; and the different forms of silicate paint are innocuous, and efficient for purposes of decoration. The colour of many pigments mixed with oil deteriorates, some tints fading whilst others deepen or turn almost black—varnish turns yellow with age. Thus the tone of the tints beneath become changed with time. A varnished wall surface loses its clearness and freshness in the course of years, though still retaining a pleasant tone; and it is otherwise of the greatest value, especially in London, on account of the ease with which it may be wiped down, and kept free from the accretion of dust. But an ordinary tinted paper with dado below and lighter colour above, hung on clean and sound walls, and varnished, is one of the best, most wholesome, durable, and cheap modes of good and simple decoration. A still less costly, but less durable

decorative medium is to be found in the washable distempers, such as the Duresco, made by the manufacturer of the Charlton-white, or the Calcarium. Their great advantage is that the colouring-matter does not rub off on the clothes, or into the air as dust. One of the most valuable of decorative media is the Crete-enamelling of Messrs. Owen, of Brook Street. Unfortunately they are not represented here. They do not like to appear to use such exhibitions as an advertisement—a lesson which might well be learnt by some whose interest in the hygienic success of the exhibition appears to be on the side of reciprocity, with one foot, at least, down in the scale; and who would seem to be pointing at themselves in sarcasm the old proverb that "Good wine needs no bush," some of their wares having far less to do with sanitation than with commercial enterprise or money-getting. The Crete-enamel is more costly than paint in the first instance, but it keeps its first freshness longer. It is perfectly innocuous, and is less absorbent even than varnish. It possesses all the advantages of varnish without its disadvantages. And when I say that in its washable form it is in fact a colour-polish, its superiority over varnish in appearance must be manifest. In its unwashable form it is still non-absorbent, but is more liable to injury though equally durable.

Paper-hangings, again, are now made washable at the small cost of one penny per yard. It is of the greatest consequence that their colouring-matter should be free from volatile mineral poisons; and that, whatever be its composition, it shall not rub off. The penalty should be sharp and heavy upon those who offer injurious paper-hangings for sale. In every case, pending legislation, the purchaser ought to demand a written or printed warranty from the vendor. It would be a new departure, in the most desirable direction, if the Sanitary Institute, or some other such body, could establish an organisation for the protection of the unlearned and unwealthy portion of the public from the supply of such deleterious things. Only a few years ago even a medical man, a tenant of mine, who had selected his own paper for the dining-room, was made seriously ill from the imperfectly-fixed colouring, of rich yellow and brown, made with orpiment of arsenic. Other members of his household suffered, as well as the men employed to remove it from the walls. It is a satisfaction to know, that except upon the score of unscrupulous trade competition, it is needless that such goods should be sold at all. There are several comparative illustrations of this in Mr. Henry Carr's exhibit, No. 852. Messrs. Woollams, Jeffreys, Heywood, and others, exhibit an ample variety of all colours and shades in a guaranteed harmless quality. In admirable decorative material we have also the Hindley's Japanese leather papers, Lincrusta-Walton, Hall's Corovellum, and others, together with a variety of damp-proof paints for interior surfaces, of questionable value in this especial respect, seeing that damp should be kept from penetrating from the outside, and not be merely covered up from sight within.

As a wholesome decorative covering for walls, a panelling of pine or fir is said to be one of the best on account of its resinous odour. But such panelling must not be allowed to become a harbour for damp stagnant air behind it. These with other woods of a harder nature have always been popular. And a beautiful variety has been introduced in Roberts's foreign and colonial importations.

But unprotected panelling becomes dangerous in case of fire. There are now, however, for woodwork invaluable safeguards against fire, such as the Asbestos paint, and the Cyanite paint, which ought to be made use of largely for wall panelling and floors. Calamitous fires have been already prevented by the employment of them. But we cannot, with all of them, quite so perfectly preserve the charming brightness and freshness of the natural grain of the wood beneath them, and, indeed, a painted surface is more commonly implied by their use, and they need, so to say, a fixing. Nevertheless, these paints give a good grounding for subsequent applications, whether paint, polish, stain, or varnish. It ought never to be forgotten that in floors it is not enough to dress only the parts which will be covered with carpet. And care ought to be taken that the dressing should be an impervious preparation of some sort or other; so that the floor may be wiped or washed without becoming saturated with water. Unless the boards are ploughed and tongued the joints should be well filled, so as to prevent draughts to the feet, the percolation of water, and, above all, the circulation of dust, to which an open joint is but too favourable. A wide field for wholesome decoration is opened up by the fibrous plaster and canvas plaster, made by Jackson and others, but their use may afford an unfortunate inducement to the finishing of a house before its newly-built walls can be properly seasoned for healthy occupation.

In conclusion, I will only say that we may well congratulate ourselves that we live in an age when colour is more prevalent and more really appreciated for its own sake than it had been for a long time previously. I have had the pleasure of throwing together a few general hints as to its application. And convinced as I am that it has been ordinarily regarded too much as a mere personal indulgence for those who can afford to spend their means upon their own amusement or gratification, I would express a hope that I have succeeded in asserting its claim to be considered one of the many requisites of a healthy home.

## WATER SUPPLY.\*

BY THOMAS H. WATSON.

THE management of water, after we have collected it and have got it delivered to our house, is the special subject of this paper.

In the Metropolis there are at present two systems of delivery—the constant and the intermittent. The latter is being gradually superseded. Much valuable information on this and many other matters connected with the subject is published in the report of Colonel Bolton, the official water examiner appointed under the Metropolis Water Act, 1871. I do not understand that any effectual power is given by Parliament to compel the companies to deliver pure water. What is wanted is not a “standard of filtration” on which the companies may agree, but a “standard of purity and softness” on which the public may rely, and also we want “requirements,” not exclusively with the object of saving water, but made also in the interests of the consumers, to facilitate the proper management of it within the house, and to insure the proper cleaning of all cisterns and tanks periodically. The periodical examination of cisterns as to their cleanliness, proper surroundings, and fittings, should be made the work of an independent public officer, acting under the direction of the sanitary authority entirely in the interest of the consumers, whether occupiers of private houses, chambers, clubs, hotels or lodgings. The great objection to the intermittent service is the much greater storage required in each house and consequent multiplication of cisterns and tanks, and the inconvenience of having to receive at a particular time the whole supply for twenty-four hours.

The constant service, however, requires fittings much improved on those which have been allowed to be used under the old system. The great hindrance to the introduction of this service is the expense and trouble involved in making the necessary alterations to the fittings to limit the waste of water.

For potable water Colonel Bolton recommends that where a constant service is given, a special supply should be taken from the mains so as to draw off water direct from the works (not from any house-cistern, where it is liable to become contaminated, or at least stale). With the constant service, however, cisterns could be wholly dispensed with. An alteration or break down in the mains may necessitate an interruption of the service at any time, and great inconvenience would be experienced if the storage within the house were not sufficient to carry over such a period, be it long or short.

The waste of water that may take place when the fittings are imperfect and the pressure is great, has led to the introduction of a throttle or ferrule into the communication-pipe, lessening the diameter of the water-way to such an extent, that when the pressure is reduced, the water may flow too slowly to be of effectual service. Some storage and a moderate pressure are, therefore, desirable. The constant system, to work effectually and economically, depends upon mutual fair dealing between the water companies and the consumers, but it is not easy to adjust things on this basis, and many persons advocate a mixed system. It is, therefore, important to consider the whole subject of cisterns and tanks.

*Materials.*

Stone, brick, or tile lined with cement, and puddled on the outside with clay, where the ground is porous, are found to be the best materials for tanks of large capacity. Soft water dissolves lime, but cement is not acted upon by any water. It may be trowelled smooth, and kept clean. For house cisterns, stone, slate, iron, lead, zinc, and other materials are used. Of these, perhaps slate is best, but it requires to be most carefully fitted and put together with slate cement and metal cramps. Iron rusts badly when alternately wet and dry; enamelled iron is expensive and uncertain, galvanised iron having a mere coating of zinc, which is dissolved by soft water, cannot be relied upon. Lead, of very ancient use, and its modern rival zinc, are also considered objectionable, and should not be used where anything better can be had. I think that stoneware is the best material for the house cistern, and as the constant supply requires only a limited storage, say 100 to 200 gallons, there should be no difficulty in the general adoption of cisterns of this material, provided they are made and fitted in a way that will admit of their proper use.

Reservoirs for spring water require to be fitted with means to aerate the water at the inlet. Large tanks must be thoroughly ventilated; all, without exception, require to be fitted with means to run the water off to the very bottom—this is called “the wash-out,” without which they cannot be effectually cleaned. A flap-valve and chain is the proper contrivance for this purpose. Tanks are usually constructed underground; it is sufficient, however, if they be half sunk in situations where the earth that results from the excavation can be heaped around and over them in a mound of sufficient thickness to protect the contents from changes of temperature.

The house cistern requires to be close covered to keep out light, dust, and vermin, and no foul air should by any possibility find

access to it. The constant service should enable us to dispense with more than one cistern in any house of moderate size, but if there are more than one the same rules will apply to all. On lifting the cover (which should be kept clean) the whole interior of the cistern should be well lighted and in full view.

Most people would be shocked could they but look in the cistern of their house, but cisterns unfortunately are not usually placed where they can be looked into: the neglect of this is simply amazing. You ask a householder when the cisterns are cleaned out, he does not know. The servant, on being appealed to, only knows that it has not been done since he has been there. I have myself examined cisterns that have not been cleaned out since the house was built though several years have run by. I have found cisterns that could not, by any possibility, be properly cleaned out at any time. I have seen those that have been “done just recently” by an under-gardener, and even a workman, and found them full of vegetable growth, an inch of mud at the bottom, and a quarter of an inch of slime on every side. The cause of this is easily discovered—until lately people had forgotten or had learnt nothing about the necessity for attending to such things, and it is just to admit that the builder, and frequently the architect, had not regarded as important the proper disposition of this part of his work. Cisterns were thrust into any out-of-the-way place, and the plumber was left to arrange his work as it would come easiest for him to execute, without the slightest reference to convenience in the subsequent use of it. Cisterns were multiplied, and the use of the water contained in them varied by subsequent “plumbers’ alterations,” so that things were brought into the utmost confusion, and discredited has resulted all round.

The system now is, to form a separate cistern room in a cool, light, and well-ventilated place in the upper part of the house; here the cistern stands just so much above the floor as will admit of the connection of pipes, and give access to it all round. The cistern itself is close covered. The arrangement I make is this—standing in front of it with the cover removed, you see the service cock near the back right-hand corner, a solid tin trumpet waste to take the overflow and form a wash-out, rises from the bottom of the left front corner; the cistern is fixed a little out of level—the left front corner about an inch lower than the right back corner—to drain the contents away completely when the waste is out. The proper cleaning and rinsing out of a cistern thus arranged is the work of a few minutes. It is to be done every three or four months. No supply pipe is taken from the bottom. At about an inch from the bottom, the supply to the hot water system is taken; three inches above this level the cold water supply is taken in a pipe of sufficient bore to serve all the lesser branch pipes. The object of this is to let the cold supply fail first in the event of any interruption of the service; there are then three inches in the depth of the cistern reserved for the hot water system until the service is renewed.

The under-waste should be syphoned below the cistern to form a trap: the pipe should be carried to some convenient place in the open air, where the end of it can be readily seen by the company’s inspector; this forms an efficient “warning pipe.” At the same time it must discharge in such a way as not to deluge the house when the contents of the cistern is being run off for cleaning.

The regulations issued by the water companies are rather misleading. They suggest that every waste-pipe must be converted into what is called an “overflow-pipe,” that is a pipe taken out of the side of the cistern near the top, and this so arranged as to act as a warning pipe. A cistern thus fitted cannot be properly cleaned out except by such an expenditure of time and trouble as is likely to cause it to be neglected altogether. In my opinion this form of waste-pipe should never be admitted. The “wash-out” and “waste,” when properly fitted, answer every requirement as an overflow, and the end of this, equally with the other, is an efficient warning-pipe when properly placed in view.

The plumber has been so accustomed to perforate the cistern when in position—considering only how he can best accommodate his work without regard to its subsequent cleaning out—that prejudice is likely to arise against the use of the stoneware cistern. I think the plumber should give way in this, and cisterns might then be kept in stock sizes, and perforated as follow, viz:—

Stock size 3 feet x 2 feet x 3 feet = 100 gallons effective capacity.

4 „ x 3 „ x 3 „ = 200 „ „ „

Angles rounded in bottom and sides—glazed brown, yellow, or white inside—provision for service-pipe and waste-pipe as before described and for two supplies on the right side, near to, but not in the front—the lower one to take connection of 1 in. pipe, the upper one 1½ inch.

For drinking-water a separate cistern is recommended. It is not sufficient that this should differ from other cisterns only in being smaller and of a glazed material. Special arrangements must be made in its construction; these must be determined by a careful consideration of its special use and the means by which it may be kept in order.

My idea is that it should be smooth and white inside, so that no dirt could rest in it undetected; glazed and rounded, that it might be readily cleaned; no larger than is necessary, and so shaped that it might be completely emptied and set in order

\* A paper read at the Conference of Architects at the International Health Exhibition.

every day; deep, rather than shallow, with a close-fitting cover going over the top rim no larger than could be safely handled with one hand.

The water required for drinking purposes as water, and in beverages as tea, coffee, &c., is estimated at 2 pints a day for each person; we may double this during hot weather, and double it again, as we need not be sparing where there is such abundance. I should say that 1 gallon a day for each person would be ample for such a cistern, or say 1 cubic foot for each multiple of five persons in a family, starting at 2 cubic feet as a useful size for a family of ten persons.

This cistern should be fitted up in the pantry, still-room, or any clean cool place in the house; its front edge should stand on a hard wood drainer, such as is found by the side of the pantry sink. Let the cistern be in full light, accessible in every part of it, and resting on a projecting bracket, which may also serve as a shelf for glasses.

The bottom of the cistern should be rounded and sloping towards the front, where a ground-in porcelain plug should be fitted so as to enable it to be completely emptied. A porcelain tap, the parts simply and easily cleaned, should be immediately over the plug, and should not draw the water quite to the bottom. The overflow should be provided for by a slight depression in the front of the rim, so that any waste may be observed as it flows down in a channel in the front of the cistern to the drainer. A glass ball ball-valve, supplied direct from the main, and not from any other cistern, completes the apparatus. This tap may be small, the metal nickel-plated, and the ball and arm must be capable of being turned up out of the way.

With a preliminary swirl round and emptying, the plug is inserted, the ball turned down, and the cover put on—the cistern is then charged. Every day, immediately before or during the intermittent supply, it is to be washed out with the remains of the last day's supply, rinsed out with the first of the fresh water, emptied again, and then set in order for the day. This would not take more than two minutes, and for that day at least the drinking water would not be perceptibly worse than that which the company supplies, while the addition of a pound of washed ice in summer time would give it just that degree of coolness that would render its use the more agreeable.

Of the other cisterns in the house I need speak but briefly. The hot-water tank should not be placed, as it frequently is, near to the cold water to affect its coolness. It is a mere accumulator or reservoir on the hot water circulation, and needs no special fitting beyond a manhole for occasional cleaning. It is best placed in the bath-room, where some of its heat may be utilised in a drying-closet.

W.C., urinals, &c., require waste preventor cisterns. All those in use need improvement. The principal objections are that the incoming of the water is attended with noise; this may be obviated by taking the delivery nozzle down nearly to the bottom of the cistern; also the noise and want of force in the flushing of the closet. The valve should be contrived near to the pan, so that a column of water is standing above the valve ready to act the moment the valve is opened.

Where there is an open boiler a feed cistern is required. It has been the practice to put this in a dark cupboard, generally near the kitchen range. For this there is no necessity. It may be placed in any open light place where it can be got at all round; it only needs to be on the level of the boiler. It must have a close-fitting cover, and be kept quite clean. Stoneware is the best material for this purpose.

Too great a pressure upon pipes and fittings causes waste of water. It is advisable, in determining the place for the cistern, to arrange that the pressure does not exceed that which is due to about 25 to 30 feet head of water. In houses of many storeys, with the hot water system, this difficulty cannot be met, and a great want is a really efficient hot water high-pressure tap.

In regard to the management of hot water there are two or three points to be observed. The flow-pipes should always be fitted to a flange joint on the top of the boiler and of the accumulator, the inner surface of which should be smoothly rimmed to prevent the formation of an air trap—the cause of the thumping and vibration often experienced. The flow-pipe should be of larger bore for a short part of its length immediately over the boiler, especially when the water is hard and much deposit is formed at the mouth of the flow-pipe. All supplies should be taken from the flow above the accumulator so as to draw the hottest water. Very short branch pipes should be admitted to hinder the dead water becoming cold and causing waste. The return should take the shortest course to the lower part of the boiler; the feed-pipe should be entered into the return so as to deliver the cold water direct to the boiler and not reduce the temperature of the whole volume stored in the accumulator. The feed should have an elbow or dip at its connection with the return, so as to hinder the hot water ascending into the cold water cistern.

#### *Stop-cocks.*

There should be a stop-cock on the "communication" pipe to enable the service to be shut off entirely. There should be a stop-cock in a convenient place on every supply taken from a cistern, to

enable the workmen to shut off the supply without interfering with the other service of the house, or emptying the cistern when alterations in any the fittings have to be made.

#### *Distribution.*

The conduits for distribution of water now in use are exclusively of iron when of large capacity, coated in various ways to hinder the action of the water in direct contact with the pipes from rusting the metal away. For soft water the pipes are coated, by Dr. Angus Smith's process, with a varnish of coal tar, or by a coating of cement or lime paid over the interior metal surface of the pipes. The joints which used formerly to be made with tow yarn and lead caulked in, are now, where the capacity of the pipe admits of it, made on the inside with cement, to hinder the increase of organic matter observed in water that was allowed to come in direct contact with the yarn. Hard water has little action upon iron pipes, a coating is formed by the earthy salts on the inside of the pipes, and contact with the metal is thereby hindered.

For the smaller pipes within the house, on the whole iron tubes are considered best. Various processes have been introduced for protecting the metal from contact with the water; where, however, the water is at all hard, the inconvenience of direct contact is soon overcome by the deposit formed on the inside of the tubes. For soft and hot water the protective processes of Barffing and galvanising are frequently used, but tubes thus treated do not admit of being worked up, or bent, without injury to the coating, and the only effectual way of employing either process is by taking down the whole of the work after it has been fitted, sending it away to be treated, and refixing the work without any alteration whatever. This becomes an expensive matter, as the cost of labour far exceeds the value of the tubes. Wrought iron may be artificially coated with a deposit of lime after fixing, and, when kept well painted on the outside, tubes of this material are perhaps the best and most economical for hot water work.

Lead in pipes is less objectionable than in cisterns, because these require cleaning, consequently the surface is liable to be exposed to fresh action of the water. Both hard and soft water generally form a coating on the inside of lead pipes, the latter by a vegetable matter, which appears to combine with the oxide of lead, and protects the water from contact with the metal. The facility with which lead can be worked, its strength, durability, and fewness of the joints required, cause it to be preferred for house-work. It is reassuring to be told by those who have made observations, that the action of water upon lead pipes is very slight when the metal is tarnished—a condition that is attained soon after manufacture—and under all circumstances is so slight as to be immaterial. Lead pipes have been made with an inner lining of pure tin. The practical objection to tubes so lined is that they do not admit of the ordinary plumber's joint, consequently their use is limited. Pure tin is the only material to use when difficulty is experienced with other metals, and expense does not stand in the way. Copper, tinned copper, and galvanised iron are not recommended.

It is important in the economical arrangement of the water-service of the house that those offices which require water-supply should be grouped together as much as possible—a point, unfortunately, too frequently overlooked, although easy of attainment when attention is given to it at an early stage of the plan.

Thus, a bath-room is to be preferred that is over a pantry, rather than one that may be more conveniently arranged on the bedroom-floor over a principal room of the house. The disposition of closets, lavatories and sinks, should follow this rule; the pipes may then be exposed and painted to suit the wall-surface, not cased up by joiner's work, or hidden under floors, as is too frequently done to get them out of view, when they have to be carried through apartments in which their appearance is not expected.

#### **LEGAL.**

##### **Cumberland Assizes.**

(Before Mr. JUSTICE MATHEW.)

SCOTT v. THE GREAT CLIFTON SCHOOL BOARD.

##### **ARCHITECTS' FEES.**

This was an action by Mr. T. G. Scott, architect, Workington, for payment of 113*l.* for professional work from the Great Clifton School Board. The plaintiff was employed by the defendants to prepare plans for the erection of an infant school with board-room at Great Clifton. The plans were disapproved by the Education Department on the ground that a board-room was not necessary for the district. A second set of plans with a house for the mistress was prepared, and finally a third set for the infant school without a house for the mistress. The erection of the school upon the third set of plans was proceeded with, the plaintiff superintending the work. After the buildings had reached a certain stage a dispute arose between the School Board and the builder and architect, the Board complaining that the stone used was a bad stone and not according to specification, and that the drains were not puddled at the joints. The Board dismissed the architect from further superintendence of the work, and they declined to pay the builder

for the work he had done. The result was that the dispute between the Board and the builder—whose contract was under seal—was referred to arbitration, and the arbitrator awarded him 34½%. The schools were completed by another builder upon the plans which had been furnished by Mr. Scott, and for which the architect now sought to be paid. The architect also claimed for superintendence, and one of the questions for settlement was whether the architect was entitled to more for superintendence than his percentage on the 34½% awarded to the builder. The plaintiff submitted that he was entitled to more inasmuch as he was wrongfully dismissed. The defendants put in a counter-claim in respect of the negligence of the plaintiff as an architect, and they denied liability altogether on the ground that the Board was a corporation, and that any contract to be binding upon them must be made under seal. The arrangement with the architect was not made under seal, and therefore the Board were not liable for the payment of the claim.

After the plaintiff had been examined, counsel consulted, and agreed, subject to the question of liability, that the amount to which the plaintiff was entitled to recover was 90%, the defendants withdrawing the counter-claim.

The counsel for the Board suggested that the question of liability on the ground of want of seal should be discussed in London, and this course was ultimately adopted.

### NOTES ON NOVELTIES.

**A Simple Fire-Extinguisher.**—Our American kinsmen must again be credited with the introduction of an invention for extinguishing fires in their earlier stages that is so absurdly simple as almost to provoke a smile; yet it is in every sense as effective as any of the small fire-engines, extingueurs, &c., made for that purpose. That efforts have been made by English and foreign inventors to introduce a reliable appliance adapted for domestic and other uses is seen by the many apparatus now before us, all of which are, no doubt, good in their way; and we should be unjust in saying a word against them, but they lack one essential in particular, and that is that their price renders them prohibitory to the great bulk of the community. There may also be weak points in some of them, such as requiring occasional recharging to keep them in order, and such like, which, unfortunately, oftentimes does not get done, and the apparatus, when the fatal time comes, is not workable. Now it is self-evident that if an inexpensive appliance could be made, not dependent on any extraneous aid, but always ready whenever wanted, self-preservation alone would induce all thoughtful persons to provide themselves with it. It may be reasonably asked, as all extingueurs are dependent upon some chemical compound for their action, if it is not possible to introduce the chemical in some cheaper form. Brother Jonathan has answered the question for us in a most decided manner. If we entered a house and noticed an ornamental-shaped bottle of coloured glass on shelf or sideboard, we may probably suppose it contained some new *bonne bouche* or cunningly-devised liquid to administer to our epicurean tastes. But what if we were told that it contained a chemical compound sufficient in all probability to extinguish any fire that could occur in that room? We should scarcely credit our informant. Yet of such a nature is the "Harden 'Star' Hand Grenade Fire-Extinguisher," that we had an opportunity of seeing in operation a few days since. It is simply a stout coloured glass bottle holding one pint of a chemical liquid which, when thrown on to a fire, will extinguish it in a few seconds, if not in too advanced a stage. Of course if one will not effect the object, two or more must be used, but in the experiments we witnessed one sufficed in each case to put out a much fiercer fire than the best friends of the invention could have expected. The experiments in question took place on a piece of waste ground adjoining the Metropolitan Railway in Farringdon Street, and in one case a hoarding had been erected, well soaked with Stockholm tar; petroleum was then soused over this, and a fire lit at the bottom with sticks and paper in the usual manner. Waiting until the whole was one mass of flame, the operator broke one of the bottles over it at the lower part, and in six seconds the whole was extinguished. Another experiment was carried out with a wooden chimney, about 1 foot square and 14 feet high, similarly coated with tar inside. Lighting a fire at the bottom and allowing the whole interior to become one blaze, with fully 4 feet of solid flame belching forth from the top, a bottle of the liquid was broken over the bottom part. This succumbed instantly; the flame at the top was immediately arrested, dwindled down, and all was over in less than a quarter of a minute. We were informed it was the first time an experiment with a chimney had been tried, and the operators were consequently as uncertain as the visitors as to the result. Two more satisfactory cases could not have happened for the success of the invention, and the visitors expressed themselves to be fully satisfied. Should the question be put to us as to what it is, we can only answer that it is a chemical fluid in an hermetically sealed bottle, that will resist a temperature of 40 degrees below zero, is perfect harmless to flesh or fabric, and is said not to deteriorate with age, or in any climate. The effect, when the contents are discharged on to a fire, is that they immediately

vaporise into great volumes of fire-extinguishing gas, so that combustion cannot exist, and the cost of these valuable little appliances is only three shillings and ninepence each. Here then we have a reliable article at a price, as we before observed, within the reach of all, and that every careful housekeeper should place in every room in his dwelling. Reverting again for a moment to the experiments, we may remark that, excellent as they were, in a covered building the results would have been even more satisfactory, for in the open air a large quantity of the vaporised gas is carried away by the atmosphere, but in a room or warehouse this could not escape, and would consequently be utilised for its proper purpose, and assist in extinguishing the fire more rapidly. In America, where the star grenades have been in use for some time, the amount of property they have assisted in saving from fire has been very large, and we hope their introduction into England will prove as great a boon to our community as well as a commercial success to the inventors. Further information respecting them may be obtained of the London agent Mr. J. S. Malcolm, Southwark Bridge Road.

### WORKS IN PROGRESS.

**Messrs. Vigers Brothers**, of Chelsea, have just supplied their imported wood-block flooring to the Board Schools, Harrow Road, Paddington, and Wilde Street, Drury Lane, W.C. The work has been carried out under the direction of Mr. Robson, the architect to the London School Board. We believe these floors, which had been previously supplied to several large schools belonging to the London School Board, are giving entire satisfaction.

**Great Eastern Railway New Hotel, Liverpool Street.**—The whole of the lifts at this building are almost completed. They have been erected by Messrs. Archibald Smith & Stevens, of Janus Works, Queen's Road, Battersea, and consist of one "Stevens and Major's" hydraulic balance passenger lift, 82 feet travel, one hydraulic luggage-lift, same travel. These receive passengers and luggage on the platform of the station, and carry them to all floors in the hotel. One hydraulic stores lift, about 70 feet travel, one direct-acting wine cellar lift, one hydraulic continuous lift for kitchen purposes, two hydraulic kitchen lifts with jigger cylinders, the whole being driven by water from a large accumulator, supplied by a set of treble barrel pumps, in turn actuated by a 6 horse-power Crossley "Otto" gas engine. There are, in addition, several hand-lifts. The whole of the contract has been erected under the supervision of Mr. T. W. Worsdell, locomotive engineer of the company.

**Westwood, near Bradford-on-Avon.**—The whole of this ring of bells have been cracked for many years. As a beginning, one has been recast by Messrs. Llewellyns & James, Bristol; and as soon as funds are forthcoming the remainder will be recast by the same firm.

### SCHOOL BUILDINGS.

**Durham.**—New buildings comprising chemical laboratory, museum, &c., recently erected in connection with Durham School, have been opened. These buildings, which were built from plans prepared by Mr. A. W. Blomfield, of London, comprise on the ground floor a museum and a modern class-room, and above a laboratory, scientific lecture rooms, and a balance room, all fitted up in a most elaborate manner, and heated by hot-water pipes. The work was executed by Messrs. Gradon & Son at a cost of about 3,000*l*.

**Portobello.**—Out of a limited number of competitive plans sent in for this school, the Board have unanimously adopted those submitted by Mr. J. M. Henry, architect, Edinburgh, and that gentleman has been instructed to proceed at once with the working plans. The building will accommodate 300 pupils, and will admit of being easily extended at any future time to receive another one or two hundred.

**Temple Cowley.**—The Education Department having required additional accommodation for 100 children, the architect (Mr. A. Mardon Mowbray, F.R.I.B.A., Eastbourne) of the present school chapel was instructed to prepare the necessary plans, &c. The work has been commenced by adding on to the west end of present girls' school an infant school, 40 feet by 20 feet 3 inches, an entrance porch, cloak-room, and lavatories for infants and girls, book-room, and offices. The style of the present building, Gothic of the early part of the thirteenth century, has been followed in the new part, the walling being of red brick, with blue Staffordshire brick bands and stone dressings, the roof being slated with red roll ridge tiles on top. The two school-rooms can be thrown into one for Divine service, penny readings, teas, &c., by the removal of folding doors, which can be converted into tables, the school desks being convertible into seats, and the infants' gallery into a platform. The flooring will be formed of wood blocks on concrete bed. Mr. A. Collett, of Oxford, has undertaken the contract. The chancel portion will be added later on, also the school-houses.

## CHURCH BUILDING AND RESTORATION.

**Bozeat.**—The work of rebuilding the church tower and re-hanging the bells of Bozeat parish church has been completed. Some five hundred years ago the present church was built and a spire placed on the old Norman tower. The latter was strengthened at various times, and fifty years ago an iron band was placed round it. In 1877 this broke, and some of the masonry of the spire fell on the roof. The spire was then taken down. The old tower also became dilapidated, and it was agreed to rebuild it. Mr. Carpenter (Messrs. Carpenter & Ingelow) prepared plans, from which Messrs. Margetts & Neale, Kettering, have erected an exact reproduction of the old structure. Local stone has been used. The tower stands 100 feet high.

**Chatham.**—The memorial-stones of a new Bible Christian Chapel and Hall in the Luton Road, Chatham, were laid on Monday last in the presence of a large and distinguished assembly. The building consists of chapel and hall with class room, vestries, lavatories, &c. It is situated on a commanding corner site, the front elevation of chapel having square buttressed tower at angle of building with turret on opposite side; large rose windows in centre of arched recess and double entrance porch; the side elevation being divided into five bays with double windows and buttresses between. The elevation of hall is of similar design to side of chapel, to which it is joined by vestry buildings and choir and organ building over. The style adopted is early English, the materials being red bricks with white stone dressings and slated roofs. The inside wood-work and seating is to be of pitch pine. Mr. J. Kingwell Cole, of 28 Mount Street, Grosvenor Square, W., is the architect, and Mr. C. E. Skinner, of Chatham, the contractor.

**Stockton.**—The memorial-stones of the new church of St. Paul have been laid. Mr. J. P. Pritchett, Darlington, is the architect of the building, and Mr. Robert Boyd, Cleasby, Darlington, the builder. It will be of bricks, in the Early English style, and includes a nave with north and south aisles, chancel, organ-chamber, and vestry. It will provide accommodation for 417 people. The following are the sub-contractors:—Masons' work, Mr. R. Boyd, of Cleasby; slaters and joiners' work, Messrs. Adamson, of Gainford; plumbers and glaziers' work, Mr. Geo. Lambert, Middlesbrough; painters' work, Mr. Metcalfe, Darlington. Mr. Smirke acted as clerk of works.

## NEW BUILDINGS.

**Birmingham.**—The rebuilding and enlargement of the Traveller's Rest public-house, situate at Lower Edward Street and Jakeman's Walk, Birmingham, is now completed. The work has been executed for Mr. Alfred Humpage, from designs by Mr. Oliver Essex, A.R.I.B.A. of Birmingham. The contractor was Mr. W. T. Bennett, of Birmingham.

**Birmingham.**—The new premises of the Birmingham and Midland Eye Hospital were opened on July 24 by Lady Leigh. The hospital is a brick building, with stone dressings embellished with a small amount of carving. It stands upon 1,080 square yards of land and has three frontages—namely, to Church Street, Edmund Street, and Barwick Street. It consists of four floors and a basement, the kitchen department being in the top storey. There are two stone staircases reaching from the main entrance to the top of the building, one passing through the side set apart for the male patients, and the other that of the female patients, and a third stone staircase leading from basement to the top storey. The out-patient department is entirely isolated from the rest of the building, the large waiting hall occupying the internal space on the ground floor is under its own roof, thus forming a large internal area to assist the lighting and ventilating of the upper floors. This waiting hall is arranged to accommodate about 250 patients daily. The hospital is arranged to accommodate beds for seventy patients, with ample cubical space per bed. Great attention has been paid to the sanitary arrangements, and the building has been furnished with a due regard to the comfort and convenience of the inmates. The building has been erected by Mr. William Robinson, builder, under the superintendence of Messrs. Payne & Talbot, architects.

**Marlborough.**—The College Chapel has been undergoing extensive alterations at the hands of Messrs. Bodley & Garner, architects, Gray's Inn, London. Messrs. Stephens & Bastow, of Bristol and London, obtained the contract to build an entirely new chancel and organ-chamber; remove the then existing roof, and raise the walls of the nave, extending the same one bay longer at the west end, with a porch and staircase up to the west gallery. During the progress of this work it was found that the old walls were of a most defective character, and not strong enough to carry the new roof, and it was therefore determined to take down the walls, and in rebuilding to widen the chapel three feet. The extreme length of the new chapel, from the apse end of the chancel to the west end-wall, will be 176 feet; the width of the nave will be 45 feet. The floor of the chapel will be laid with Stephens's registered wood-block flooring, as used in large hall and classrooms at Charterhouse Schools, Godalming; dining-room and

laundry, Wellington College; and reception-rooms, Heathermead, Berkeley. The clerk of works is Mr. Knight, and the cost of the contracts will be upwards of 20,000*l*.

**Rugby.**—The Hospital of St. Cross, the gift to the town of Rugby by Mr. and Mrs. R. H. Wood, of Penrhos House, has been opened. It is built of red bricks, with dressings of Bath stone, and has been designed by Mr. Henry Wilson, of Gray's Inn Square, London. Roughly described, the ground plan is that of a long rectangular block running east and west, with two large projecting blocks on the south, an arrangement which permits of the free circulation of air around every room in the hospital. The building is of three storeys height, and the ground floor is appropriated to the use of male patients, the house surgeon, and the matron; the first floor to that of female patients, while nurses and servants are provided for on the second floor. In the projecting blocks there are four principal wards, each intended for the accommodation of seven patients, and two smaller wards contain severally one and two beds. The builders were Messrs. J. Parnell and Son, of Rugby.

**Sheffield.**—A limited number of architects have been invited to submit plans in competition for a Wesleyan Sunday-school and mission-hall, on condition that the one who sent in the best plan should be employed in the erection of the buildings, and that each of the others should receive a fixed payment for preparing the design. An examination of the plans received has resulted in the selection of the one by Mr. C. J. Innocent, architect, 17 George Street, Sheffield, and the building is to be proceeded with immediately.

## GENERAL.

**M. Frania**, the marine painter, has died at Brussels. His studio was much frequented by English pupils.

**The Meissonier Exhibition** in the Rue de Sèze, Paris, will be kept open until August 15. It was originally proposed to close the gallery on July 24.

**Mr. P. D. Puech** has obtained the Grand Prix de Rome for Sculpture. Last year he obtained the "Premier second grand prix."

**St. Hilda's Abbey, Whitby**, was on Saturday visited by the York Architectural Association.

**A New Opera House**, to seat 2,200 persons, is to be erected in Chicago, at an estimated cost of 250,000 *dols*.

**The Birmingham Architectural Association**, on Saturday last, made an excursion to Wolverhampton, and visited the Fine Art Exhibition. Amongst those present were Messrs. Franklin Cross, O. Essex, F. W. F. Newton, H. H. McConnell, C. E. Bateman, and V. Scruton. The party afterwards visited St. Peter's Church and other buildings in the town.

**The Statue of Voltaire**, which was modelled by M. Caillé, is to be cast in bronze by M. M. Thiébaut, and erected on the Quai Malaquais, Paris. The pedestal will be designed by M. Formigé.

**M. Paul Haag**, the projector of a metropolitan railway for Paris, is to be appointed engineer in chief of roads and bridges in France.

**The Road Surveyors of Scotland** have formed an association for the consideration and discussion of all questions connected with road management. Mr. A. Stevenson, of Ayr, has been appointed secretary.

**The Tender of Messrs. Robert Neill & Son**, of Manchester, has been accepted on the recommendation of Mr. Henry Shelmerdine, architect, of Liverpool, by the directors of the Lancashire and Yorkshire Railway Company, for the new Exchange Station Buildings Hotel and offices, Tithebarn Street, Liverpool. The amount of the estimate is close upon 100,000*l*, and the work will be proceeded with at once.

**The Freehold House**, No. 63 Lincoln's Inn Fields, was purchased in 1758 for the sum of 1,721*l*, by Mr. Norton, a barrister, who afterwards became Speaker to the House of Commons, and subsequently the first Baron Grantley. It was put up to auction on Wednesday by Messrs. Driver & Co., of Whitehall, and realised the sum of 13,000*l*.

**The Island of Herm** was offered for sale on Tuesday at the Mart, Tokenhouse Yard, by Mr. Tewson, of the firm of Debenham, Tewson & Farmer. As the highest bidding was only 5,900*l*, it was announced that no sale would take place.

**The Congress** at Dublin of the Sanitary Institute will open on September 30, when an address will be delivered by Sir Robert Rawlinson. The presidents of the sections are Dr. Grimshaw, Mr. C. P. Cotton, C.E., and Dr. C. A. Cameron. Mr. T. Drew, R.H.A., is one of the honorary secretaries.

**The Improved Industrial Dwellings Company (Limited)** now possess 34 estates in various parts of the metropolis, on which 4,314 dwellings have been erected and are in occupation, and 656 are in course of erection, making a total of 4,970 tenements. When these are completed, the number of persons residing in the company's dwellings will be about 25,000. The expenditure on capital account has reached 866,281*l*.

# SUPPLEMENT

TO THE

# ARCHITECT.

## CONTRACTS, COMPETITIONS, AND TENDERS.

LONDON, AUGUST 2, 1884.

### COMPETITIONS OPEN.

**NORTH SHIELDS.**—Aug. 18.—Plans are required for Alterations and Additions to the Workhouse. Mr. Christopher Scott, Guardians' Hall, North Shields.

**STOCKPORT.**—Sept. 15.—Designs are invited for Public Baths. Premiums of £50, £30, and £20. Mr. Walter Hyde, Town Clerk, Stockport.

### CONTRACTS OPEN.

**ABERDEEN.**—Aug. 11.—For Additions to Midmar Parish Church. Messrs. Matthews & Mackenzie, Architects, 255 Union Street, Aberdeen.

**ASHTON-UNDER-LYNE.**—Aug. 4.—For Building Two Semi-detached Villas, Fairfield, and Eight Houses, Ashton. Messrs. T. D. & J. Lindley, Architects, Ashton-under-Lyne.

**BELFAST.**—Aug. 14.—For Building School. Messrs. Young & Mackenzie, Architects, Donegall Square East, Belfast.

**BIRMINGHAM.**—Aug. 28.—For Erection of Kitchen and other Buildings at the Workhouse. Mr. W. H. Ward, Architect, Paradise Street, Birmingham.

**BURNLEY.**—For Building Loom Shed and Appurtenances. Messrs. Potts, Pickup & Dixon, Architects, Clegg Street, Oldham.

**CARDIFF.**—Aug. 8.—For Additions to Infectious Wards at the Workhouse. Messrs. James, Seward & Thomas, Architects, St. John Square, Cardiff.

**CLAPHAM.**—Aug. 6.—For Erection of Buildings, &c., at the Parish Yard. Mr. A. Corsellis, Clerk to the Wandsworth Board of Works, Battersea.

**CROYDON.**—Aug. 7.—For Building Swimming Bath and Works in connection, South Norwood. Mr. C. M. Elborough, Town Clerk, Croydon.

**DENTON.**—For Building Residence. Messrs. T. D. & J. Lindley, Architects, Ashton-under-Lyne.

**DROYLSDEN.**—Aug. 4.—For Building nine Cottages and Branch Store. Mr. F. Smith, Architect, Bridgewater Chambers, Brown Street, Manchester.

**DUNFERMLINE.**—Aug. 4.—For Building Dwelling-house on Farm of Stenhouse and other Works. Mr. Scobie, Architect, Dunfermline.

**GATESHEAD.**—Aug. 6.—For Additions to Stationery Stores. Mr. William Bell, Architect, Central Station, Newcastle-on-Tyne.

**HUDDERSFIELD.**—Aug. 6.—For Conversion of Premises into Shops and Offices. Messrs. John Kirk & Sons, Architects, Huddersfield.

**HUNSLLET.**—Aug. 7.—For Building twenty-two Houses. Mr. John E. Leak, Architect, Hunsllet.

**LANTRISANT.**—For Additions to Dinas Mixed Schools. Mr. J. J. Evans, Architect, Maesyrfrwd, Treorkey.

**LONGTON.**—Aug. 20.—For Building Relief, Vaccination, and other Offices. Mr. E. Scrivener, Architect, Howard Place, Hanley.

**LUCTON.**—Aug. 19.—For Additions to Foundation School. Mr. F. R. Kempson, Architect, Hereford.

**LYDD.**—Aug. 4.—For Building Wesleyan Chapel and School. Mr. Charles Bell, Architect, 9 New Broad Street, E.C.

**MACDUFF.**—Aug. 8.—For Building Town Hall. Messrs. Pirie & Clyne, Architects, 123½ Union Street, Aberdare.

**MEXBRO.**—Aug. 4.—For Construction of Ejector Station, Engine-house, Boiler-house, Chimney Stack, Subsidence Tanks, and other Works in connection with Sewage Scheme. Mr. G. White, C.E., Market Hall, Mexbro.

**NABURN.**—Aug. 6.—For Erection of Villa Residence and Farm Buildings. Mr. William Brown, Architect, City Chambers, Clifford Street, York.

**NEW BRIGHTON.**—Aug. 7.—For Building Shelter-houses and other Works at Landing Stage. Mr. A. Dowson, C.E., 3 Great Queen Street, Westminster.

**NEWPORT.**—Aug. 4.—For Additions to Board Schools. Messrs. W. G. Habershon & Fawckner, Architects, Park Square, Newport, Mon.

**NORTHAMPTON.**—For Additions to Malt Kiln, &c., Woburn Sands. Messrs. H. Stopes & Co., Architects, 24A Southwark Street, S.E.

**SHEFFIELD.**—Aug. 5.—For Rebuilding Shops and Premises. Messrs. Flockton & Gibbs, Architects, 15 St. James's Row, Sheffield.

**SOUTHAMPTON.**—For Erecting Stone Wall, Iron Railing, &c., for Extension of Cemetery. Mr. W. B. G. Bennett, Borough Surveyor, Southampton.

**STRETTFORD.**—Aug. 5.—For Building Cemetery Chapel and Registrar's House. Messrs. Bellamy & Hardy, Architects, Lincoln.

**SWADLINCOTE.**—Aug. 9.—For Extension of Market Hall Premises. Mr. James Nixon, Architect, Church Gresley.

**THORNTON.**—Aug. 6.—For Additions to Schools, Thornton and Denholme. Mr. John Drake, Architect, Queensbury, near Bradford.

**TYLORSTOWN.**—Aug. 11.—For Building Methodist Chapel. Rev. W. Jones, Ton Ystrad.

**WELLINGBOROUGH.**—Aug. 4.—For Construction of Gas-holder Tank. Mr. S. H. Kimbell, Secretary to the Gas-light Company, Wellingborough.

**WIMBLEDON.**—Aug. 26.—For Building Press House, Cake

Shed, and Plant for Treatment of Sewage Sludge. Mr. W. H. Whitfield, Local Board Offices, Broadway, Wimbledon.

**WOODFORD WELLS.**—Aug. 6.—For Extension of All Saints' Church. Mr. E. Egan, Architect, Loughton.

**WYKE.**—Aug. 12.—For Erection of Coastguard Buildings. Director of Works Department, Admiralty, Whitehall.

### TENDERS.

#### BARNES.

For Repairs to School Board Schools, Barnes, S.W. Mr. FRANK E. THICKE, Architect.

Hunt	£154	0	0
Alchin	139	10	0
Sale	134	5	6
Stansby	133	15	0
HILL (accepted)	116	5	0

#### CARLISLE.

For Joiners' Work required in the Erection of Stables, Wagon and Van Sheds, &c., Caldewgate. Carlisle, for Messrs. Carr & Co., Biscuit Manufacturers. Mr. T. TAYLOR SCOTT, Architect.

Latimer	£1,390	15	0
Batey & Forster	1,226	0	0
Scott	1,197	8	0
W. Court	1,172	0	0
H. & R. COURT (accepted)	1,170	0	0

#### CLIFTON.

For the Re-seating of Clifton Parish Church. Mr. J. C. MONCRIEFF, A.R.I.B.A., Architect, 23 Nicholas Street, Bristol.

	Pitch Pine.	Oak.
Smith & Co.	£1,377 0 0	£1,937 0 0

AWARDED SEVEN PRIZES FOR SUPERIORITY, INCLUDING PARIS GRAND MEDAL, 1878, THE CERTIFICATE OF MERIT OF THE SANITARY INSTITUTION OF GREAT BRITAIN, AND THE AWARD OF MERIT AT THE INTERNATIONAL EXHIBITION, 1881.

TO ARCHITECTS.—THE BRICK of the FUTURE, that shall not get dingy or sooty like other Bricks, but, being of a Semi-Vitreous nature, will maintain a clean and washable surface.

## FACING BRICKS AND BRICK ORNAMENT OF TRUE TERRA-COTTA, AS ALSO ARCHITECTURAL WORK, IN WHITE AND WARM-TINTED BUFF.

Made from the Finest Terra-cotta and Stoneware Clays, of a warm and pleasing appearance, of beautiful and superior quality and finish, non-absorbent, acid, fire, and alkali proof, will resist the most severe frosts, and when tested were found to withstand a pressure of 445 tons to the square foot. They have been used in the most exposed parts on the North and South Coasts, and being true Terra-cotta, are warranted imperishable.

Pattern Sheets and Price Lists of superior Glazed Stoneware Sanitary Pipes, and Fire Clay Goods, Chimney Tops, &c., on application.

Sole Manufacturers—CANDY & CO., Limited, GREAT WESTERN POTTERIES, NEWTON ABBOT, AND 11 QUEEN VICTORIA STREET, LONDON, E.C. Who are also Sole Makers of the celebrated "Granite Vitrified" Paving Bricks for Yards, Stables, and Footpaths, and "Granite Vitrified" Damp-proof Building Bricks, as used by H.M. Government for dock construction, &c. Samples free to Architects and Engineers.

**HALDEN.**

For Building Wesleyan Chapel, Halden, Kent. Mr. JAMES WYER, F.R.I.B.A., Architect, 9 Victoria Chambers, Westminster, S.W. Quantities by Mr. C. G. Maylard, 21 King William Street, Strand, W.C. BINGHAM, Headcorn (accepted) . . . £496 15 3

**HARRINGTON.**

For Building Wesleyan Chapel with School-room, Class-rooms, and other Offices, Harrington. Messrs. SCOTT & MURRAY, Architects, Victoria Buildings, Workington.

*Accepted Tenders.*

Ferguson, Workington, mason-work . . . £680 0 0  
Simon, Harrington, joiner-work (without upholstery) . . . 300 0 0  
Pratt, Harrington, painting and glazing . . . 90 0 0  
Blacklock, Harrington, plastering . . . 85 0 0  
Mandle, Maryport, slating . . . 72 0 0  
Whittle & Son, Workington, ironmongery . . . 52 0 0  
Walker, Workington, plumbing . . . 48 5 0

Total . . . £1,327 5 0

**HAWICK.**

For Erection of Municipal Buildings, Free Library, and Public Hall, Hawick. Mr. JAMES CAMPBELL WALKER, Architect, 2 N.E. Circus Place, Edinburgh. Quantities by Messrs. Lorimer & Fairbairn, Edinburgh.

*Accepted Tenders.*

Marshall & Sons, mason-work . . . £4,343 0 0  
Ingles & Sons, carpenter and joiner . . . 2,450 0 0  
Davidson & Son, plastering . . . 430 0 0  
Murray, plumber . . . 293 5 0  
Murray, slater . . . 254 18 0  
Guthrie & Son, gas-pipes . . . 84 0 0  
Concrete floors and stairs, tile floors, tiles on walls, heating, sun lights, ventilation, lightning-conductor, bells, speaking tubes, seats in Burgh Court, painting outside woodwork of spire, safe, iron door, &c. . . 933 10 0

Total . . . £8,878 13 0

Architect's estimate, £9,000

**HITCHIN.**

For Building Lock-up, &c., at Hitchin. Mr. URBAN A. SMITH, County Surveyor, Hertford. Quantities by Mr. Alfred Burr.

Twelvevrees, Biggleswade . . . £6,060 0 0  
Glascock & Son, Bishop Stortford . . . 6,020 0 0  
Stanleth. Hitchin . . . 5,765 0 0  
Hicks, Peterboro' . . . 5,725 0 0  
Turner, Watford . . . 5,397 0 0  
Gray, Hertford Heath . . . 5,200 0 0  
Bunting, Penstanton . . . 5,100 0 0  
Redhouse, Stotfold . . . 5,010 0 0  
Ranson, Arlesey Siding . . . 4,998 0 0

**LIVERPOOL.**

For Heating Hall and Dining-room, also Conservatory, for Mr. N. Davies, Whitechurch.

RENTON GIBBS, Liverpool (accepted).

For the Heating of Bidston Parish Church, Cheshire.

RENTON GIBBS (accepted).

## GRUNDY'S PATENT WARM-AIR VENTILATING FIRE GRATE.

The novelty, superiority, and advantage of this patent  
consist in the heating surface being greater than any  
other Fire-grate introduced to the public. It is very  
simple in construction, and is made in the form of a Stove,  
the back of which is semicircular in shape, with gills  
behind and smoke-nozzle on top, all cast in one piece.  
The same can be attached to any design of a Register or  
Stove front. It is very suitable for schools, class-rooms,  
waiting-rooms, hospitals, offices, dormitories, and dwelling-  
houses, from the cottage to the mansion. Design and  
specification post free on application.

## TESTIMONIALS.

"9 Victoria Chambers, Westminster, S.W.  
"June 10, 1884.  
"SIR,—I have much pleasure in testifying to the  
efficiency of your patent Warm-Air Fire Grate. It has  
been very successful, and given every satisfaction where I  
have used it. Yours, &c.  
"JAMES WEIR, F.R.I.B.A.

"To Mr. Grundy."  
"Baptist Chapel, Clapham Common, London. Richard  
Webb, Pastor, 10 Grafton Square.

"February 15, 1884.  
"DEAR MR. GRUNDY,—I have pleasure in testifying to the  
excellency and efficiency of your patent Fire-Grate. It is  
the most charming invention for heating a large room I  
have ever known. I shall have pleasure in showing it to  
anyone who wish to have their schools or rooms pleasantly  
and efficiently heated."

Apply to JOHN GRUNDY, 30 Duncan Terrace, City  
Road, London.

Address—YOCKNEY & CO., Corsham Down Quarry, Wilts.

## "SANITAS"

THE HOUSEHOLD DISINFECTANT.

Sanitary Institute Medal, Exhibition, 1882.  
Silver Prize Medal, National Health Society, 1883.  
Award, International Medical and Sanitary  
Exhibition, 1881.

Colourless — Non-Poisonous — Gives no Stain.  
Disinfecting Fluids, Powders, soaps, Ointments, Furniture  
Cream, Fumigators, &c. &c.

AS SUPPLIED TO 600 PUBLIC HEALTH  
BODIES.

The Sanitas Co., Limited, Bethnal Green, E.

"STOVE" CATALOGUE AND TESTIMONIALS FREE.

## "ABBOTSFORD" GRATES.

**MAPPIN & WEBB**, 158 to 162 Oxford Street, London, W.

A large Stock of these Grates, which are unsurpassed.

NONE ARE GENUINE EXCEPT BEARING REGISTERED TRADE MARK "ABBOTSFORD."

WOOD CHIMNEY-PIECES WITH OVER-MANTELS—Special Designs.

MARBLE, SLATE, AND IRON CHIMNEY-PIECES.

BRASS FENDERS, FIRE-IRONS AND DOGS, ALSO GAS FITTINGS

Specialty-designed Tile Hearths and Slabs for Sides.

**DE MORGAN ART TILES.**

# BELL'S ASBESTOS.

### BELL'S ASBESTOS FLOORING FELT.

This article is manufactured from specially prepared Asbestos fibre, and by its use any building can be rendered comparatively fireproof at a very small cost. This material should be used as a substitute for brown paper under the carpet, and it can be taken up and relaid as often as required; it may be laid between the flooring boards, on the ceiling before plastering, and on the walls. Doors of pine or other wood should be so constructed as to have a sheet of the felt in the centre, so that either side being burned the other remains intact. In houses so protected fires would be localised to the rooms in which they originate. Asbestos felt, being a non-conductor of heat, is superior to any other sheathing, and used under slates has no equal. It yields no dust, lies quite flat, is soft to the tread, and its low cost places it within the reach of everybody. Made in rolls of 36 inches wide.

### BELL'S ASBESTOS BOILER AND PIPE COVERING COMPOSITION

for coating every class of steam pipe and boiler. Non-combustible, and easily applied when steam is up; adheres to metals and preserves them from rust; prevents the unequal expansion and contraction of boilers exposed to weather; covers 50 per cent. more surface than any other coating, and is absolutely indestructible. It can be stripped off after many years' use, mixed up again with 20 per cent. of fresh, and applied again. The composition is supplied dry, and only requires to be mixed with water to the consistency required for use.

A horizontal boiler, 17 ft. 6 in. long, 15 H.P., gave the following results:—

Temperature on Plates .. .. .	186 deg.
Covering .. .. .	94 "

One ton of coal was saved per week, and, although the fire was raked out every evening 20 lbs. of steam were in the boiler next morning.

The following testimonial refers to this covering:—

Offices of Wimbledon Local Board, Wimbledon, Nov. 28th, 1883.  
Dear Sir.—It may interest you to know that we save exactly 40 per cent. in fuel through using your covering.—Yours truly,  
W. SANTO CRIMP, C.E., F.G.S.

**BELL'S ASBESTOS PAINT**, for floors, stairs, and all interior woodwork, to prevent the spread of fire. This paint is especially useful in cotton mills, and in fact in all factories and buildings exposed to risk from fire. It is quite free from poisonous ingredients, and is both easily and cheaply applied. Bell's Asbestos Paint has, on several occasions, done great service in preventing the loss of life and property. The great fire in Buchanan Street, Glasgow, in November last, produced the following testimony to the value of this material:—

Offices of the *Glasgow Herald*, the *Weekly Herald*, and the *Evening Times*, Glasgow, Nov. 14th, 1883.  
Mr. John Bell.  
Sir.—As one of the means that helped to save our buildings extending from Buchanan Street to Mitchell Street from the recent great fire, I think it fair to say that your Asbestos Paint, which was applied to the outside hoist of the *Evening Times* cage-room and other portions, gave valuable proof that it materially aided in resisting the flames from the immediately adjoining tenement while the fire was rapidly destroying it and threatening us in the most serious form. Since the fire, and to assure myself further of the value of the Asbestos Paint as a fire-resister, I placed a piece of wood, with your paint put on more correctly than in our case, into one of our furnaces, with the result that it was brought out without a fibre of the wood being touched, while similar pieces of wood, thrice coated with Irish Lime, at once got into a flame.—Yours truly,  
(Signed) ALEX. SINCLAIR.

**BELL'S ASBESTOS SASH-LINE CORD** is unaffected by heat and damp, and renders unnecessary the use of metallic wire and chains. Ropes made in the same form have great tensile strength, and being indestructible by fire are of incalculable value for fire escapes.

### BELL'S ASBESTOS.

The goods of this house are of the highest quality only, and no attempt is made to compete with other Manufacturers by the supply of inferior materials at low prices. All orders must be sent direct to the undermentioned depots, and not through agents or factors.

### BELL'S ASBESTOS AND INDIA-RUBBER WOVEN TAPE AND SHEETING

for making every class of steam and water joint. It can be bent by hand to the form required, without puckering, and is especially useful in making joints of manhole and mudhole doors on boilers; also for large "still" joints, where boiling fat and steam have to be resisted. It is kept in stock in rolls of 100 feet, from 1/4-in. to 3-in. wide, and any thickness from 1/8 in. upwards. Manhole covers can be lifted many times before the renewal of the jointing material is necessary. The same material is made up into sheets about 40 in. square, and each sheet bears the trade mark, without which none is genuine. It is very necessary to guard against imitations of this useful material, and to secure themselves against being supplied with these less useful articles at my price, users are recommended to see that every 10-ft. length of the Asbestos Tape purchased by them bears the trade mark.

**BELL'S ASBESTOS CEMENT** for the backing of firebricks and furnaces. The use of this fireproof material saves the expense and annoyance occasioned by the repairs so constantly required in the firebricks and kitchen ranges of private houses. Any labourer accustomed to handle other cements can apply this.

**BELL'S ASBESTOS BOILER PRESERVATIVE.**—This useful mixture, by absorbing the free oxygen that is in the water, entirely checks pitting and corrosion. It also disintegrates incrustation so immediately as to prevent its adhering to the plates. Not only is a great economy of fuel effected by keeping boilers clean, but the risk of having the plates burned is thereby obviated. It has been computed that 1-16th inch thick of incrustation causes a waste of 15 per cent. of coal; 1/4 inch thick, 60 per cent.; and 1/2 inch, 150 per cent. Thus the Preservative avoids the great risks which are inseparable from scaled plates, lengthens the life of a boiler, and covers its own cost a hundredfold by economy of fuel. It is entirely harmless, and has no injurious action on metals. It can be put into the feed tank or boiler, as may be most convenient. Sold in drums and casks bearing the trade mark, without which none is genuine.

**BELL'S PURE ASBESTOS CLOTH**, for protection against the spread of fire. Iron curtains warp, and in the great emergency of fire will often be immovable. Asbestos cloth, being incorruptible, will remain strong and flexible for an indefinite period, and will stay the progress of a fire and the passage of smoke longer than any other known material. This cloth is also extensively used in Maignen's unequalled water filters, for which a gold medal and diploma of honour were awarded by the Special Commission appointed by Her Majesty's Government to receive the reports of the International Juries at the Fisheries Exhibition. By special arrangement with Mr. Maignen, his filters for houses, factories, and towns are supplied by this firm.

**BELL'S ASBESTOS BLOCK GAS FIRES.**—The Asbestos Block Gas Fire is formed by placing inside the ordinary grate a hollow block (burner), composed of Asbestos, and perforated. An iron sole-plate, with a single gas burner, is fixed at the bottom of the block. After being lighted a short time, both the block and asbestos fuel throw out intense heat.

**BELL'S ASBESTOS FUEL** for gas fires. This genuine Asbestos Fuel is composed of the finest hand-picked Asbestos, and its weight is about half that of any other Asbestos fuel.

**BELL'S SPECIAL LONDON-MADE ASBESTOS MILLBOARD**, for dry steam joints, made of the best Asbestos fibre, is well-known for its toughness and purity, and is absolutely free from the injurious ingredients frequently used to obtain an appearance of finish, regardless of the real utility of the material. Made in sheets measuring about 40 in. square, from 1-64th in. to 1 in. and 1/2 millimètre to 25 millimètres thick. Each sheet bears the Trade Mark.

## READING CASES FOR THE ARCHITECT.

Price Two Shillings.—Office: 175 Strand, London, W.C.

# The Architect.

## THE LESSON OF THE GREAT COMPETITION.

IN a great architectural competition such as that which has just been decided, the public interest does not cease when the decision is attained; in some respects it only begins. The personal question of success is not a public one at all. Nor is the question whether the best man wins a public one; although indirectly it may have important bearings upon future practice, yet for the moment it is but part of the narrow issue who shall gather the gains. When the competition itself, so to speak, is at an end altogether, its artistic elements remain, in another capacity, as public, no longer private, property, the property of criticism, and, if worthy, of history.

Having regard to the magnitude of the building, the high character of its purpose, the favourable nature of the site in some degree, and the dignified way in which the proceedings have been conducted, the Government Offices Competition of 1884 cannot but be recognised as one of the most important contests of the kind that have taken place in this country; and what we now have before us is a very considerable collection of designs—the best that the profession can produce—namely, nine fully worked out in detail, and as many as 119 others in the almost equally serviceable form of sketches. The smaller number are already on exhibition to the public, and the best of the larger number, we hope, will in one way or another soon be in like manner submitted to that general inspection as works of honour which, after all, is the supreme reward for the exertions of the competitors as a body.

One very material advantage which is exhibited in Government competitions of high class is that the embarrassing restriction of expenditure is not introduced. Commercially there is no doubt a good deal that may be said about the necessity for defining the cost. It is otherwise to be supposed that one competitor may sail away boldly into the ocean of extravagance, while another conscientiously hugs the coast of common sense and is lost in the shadows and shallows of modesty. In some cases there may be a substantial difficulty here—which we do not care just now to dwell upon; but when the Town Council of Glasgow, for example, made so very much of it as they did, there are many shrewd observers who will be disposed to say, now that we have all had time to think it over, that they virtually shipwrecked their enterprise by throwing round it the trammels of needless and illusory illiberality. The same may be said of the case of the Dublin Museum, in which at this moment the last “successful competitor” finds himself in the provoking condition of being wholly thrown over by the estimating surveyors, and some of the next in order of selection in the almost equally unenviable position of being only the next in order for the same sordid trial. In fact a competitor in such a case is sometimes harassed to that degree by what may positively be called a fear of punishment—the punishment of annihilation for the offence of not being able to meet an arbitrary demand of price—that his design gives so little satisfaction to himself as to induce no hope of its giving much to anyone else. In the present case, therefore, there has been at any rate none of this pettifogging element for the competitors to contend against.

A consideration in the other direction which has already been a good deal discussed, although upon necessarily indefinite ground, is the allegation that many of the most meritorious designs, artistically regarded, amongst the number of 128 sketches first sent in, were set aside upon a certain test of internal arrangement, which, apart altogether from the personal interest of the rejected competitors, may have deprived the public of the opportunity of possessing in the end, after a little modification, anyone of half a dozen very superior examples of the building art. This may be so, and it is pretty well understood that some say it is so who ought to know; but such a misadventure has always been one of the hazards to be faced, and all we can say is that we hope the public will see these

rejected designs in all their honour now, and so be enabled to bestow upon them all the praise they deserve, and upon their authors all the distinction. The crowning misfortune of the Glasgow competitors was that an exhibition of the designs was rudely discouraged, and as far as possible prohibited, by the parochial personages to whose unwonted custody a great deal of refined architectural intelligence from all over the three kingdoms had been persuaded to commit its professional honour; and for this reason, except within the narrow limits of the town, this great and, to the profession of architects, very costly contest produced none of the good results that were expected to accrue to the competitors at large. As regards the history of architecture, the manifestation was simply smothered in local reek. But in the case now in hand, in the more generous metropolis, and under the control of the nobler authorities of Whitehall, we hope to find the utmost done to give historical effect to what is unquestionably a prominent effort for the good of the grand art concerned.

The question for the friends and students of architecture now to take into consideration, in comparing with each other, and with other similar products of the genius of the age, the fifty or sixty designs for the Offices of War and Admiralty which it is to be hoped may now come before the public is, beyond all others, this: At the present critical time, what is the direction in which the art is moving?

Now, leaving out of account, of course, all branches of ecclesiastical work, it may be accepted as a fact, so far, that what is loosely, sometimes very loosely, called Classic, is the new style whose development is to be looked for. How exceedingly loose such phraseology is—how difficult it is to say what Classic is really understood by the architectural multitude to be, or what it is desired to be—is a point that can be appreciated by very few, if we may judge by the everyday work to which the name is given; but it must have struck many of the more observant of ordinary students whose recollections are more than a very few years old, that the mode called Secular Gothic still exercises a potent secret influence over the best designers in England. It may even be said, and entirely without paradox, that this style had less influence in its own day than it has now. In other words, the artistic motive which, in the days of Mediæval detail, strove so hard to confer upon building what was thought to be a Mediæval character, now unconsciously remains in force, with Classic detail, or something like it, to divert the spirit of the art into a course that is quite uncongenial to Classic taste. Under this *régime* a few years ago, any façade of considerable extension came to be, although on the drawing-board a composition of many parts, in the reality of execution a mere flat wall upon which this composition was developed only in thin projections, without even the shadows of the paper drawing, with a turret or pinnacle, gable or gablet, thrown up against the sky of no more actual substantiality than perhaps the meagre sham buttresses and shallow breaks which formed the vertical lines. Under the new *régime*, it is only necessary to say the same thin principles still govern, and the only difference is that the genuine Mediævalists denounced the practice loudly enough, whereas the new Classicists do not yet appear to see how the fault, opposed as it was to the idea of Gothic, is much more opposed to the spirit of Classic.

The French have never fallen into this bad habit. Not only in sky-line, but in solid roof-masses, and, whenever the scale of building would allow, in equally substantial plan-masses, their composition is composition in the solid, and not in the mere flat at all. Their shadows of design are real shadows of building, and not conventional deceptions of etching. Their forms are real forms of building, and not anything represented anyhow to suit the paper purpose. Their Gothic, what little there is of it, has been as honest as this could make it, and their Classic has never been otherwise. True architecture, in a word, is a thing of the solid and not of the flat. It was one of the merits of STREET, for instance, that he saw this so very clearly; and when SCOTT was at his weakest, he forgot this the most.

Now, shutting one's eyes for the moment to all the detail of the designs at present on exhibition, and reserving himself with entire freedom for those others which he hopes to see likewise, what the student of the art has to ask himself is whether the new building is to be a design in the solid or one in the flat. If it is to be no better than the generality of the Glasgow designs—so many straight street walls, pierced with windows and doors, and manipulated into an apology for solid com-

position by means of half-attached columns as the height of luxury, pilasters meaning nothing and pediments meaning almost less, symmetrical breaks of a few inches in depth, turrets that might as well be chimneys, sham roofs, and sham towers stupendous from whose useless summits not even the voice of the muezzin calls to prayer nor a fire-bell tolls to call the engines, let him think earnestly as an artist, and say plainly as a man of business, whether this is worthy of the manly vigour of our island and our age. If, on the other hand, he can discover a design here and there amongst the rest in which the plan of masses on the ground and the grouping of masses above go hand in hand in the form of real solid architectural composition, which has an honest story to tell and tells it honestly for what it is worth, even if the result on paper may not be so attractive, let him think again whether a little of this kind of substantial virtue does not go infinitely further than any amount of showy paper counterfeits. We are emerging from the overwhelming ocean of sham into which English building fell in the Tudor and Elizabethan Renaissance. Compo is gone with blank windows and cast-iron ornaments; the mysteries of four oils and an adroit imitation are almost unknown to the rising generation; plaster groining, neatly lined in ashlar, our young Gothicists may think never existed; and certainly there are at this day cast-iron domes and even cast-iron spires in the United States, and elsewhere also, whose sublimity of sham English intelligence never reached. But England has a good deal to do in a hundred ways nevertheless, before we can hope to be able to say that our public buildings carry a surface of natural art upon a frame of natural science; and no opportunity ought to be lost for impressing this upon the professional mind. No adverse criticism by innuendo of any of the nine designs now on exhibition is for a moment intended in this argument; but all the more on that account may we leave the critical lesson they afford in the hands of those of our readers who are able to see the way of the next generation, if not the present, to assume in our admirable art the high position which alone is worthy of our country.

### GEOMETRIC ORNAMENT.

By LEWIS F. DAY.

THE necessity for a geometric basis of ornamental design has been so rigidly insisted upon by departmental authority that the student is like to be irritated into opposition: all dogma cuts two ways. In one important division of design geometry is inevitable. Wherever, that is to say, a pattern is repeated a number of times, a geometric succession of the parts becomes apparent; and where this consideration of geometric order has not been duly considered the result is often most disastrous. Suppose you commence without any idea of formal distribution, and merely design a scroll as graceful as may be—a series of such scrolls side by side will most likely show lines not in the least contemplated by the designer, and as inelegant as they are unexpected. So commonly is this the case, that it is really wisest to base your design upon some regular arrangement of lines which, if they should be apparent in the finished design, will at least be comely.

It is one of the strangest things in the experience of a designer to see the tricks his patterns will play him when repeated. A wall-paper design, for example, which appears to be so evenly distributed as to show no leading features of any kind, will prove, when hung, to run in lines slanting so as to give the impression that the walls are not true, or that the paper has been hung askew. It is not impossible, of course, however difficult, to design an absolutely free scroll that shall yet conform to all decorative conditions, even when repeated many times over. But one thing is imperative, namely, that the parts which appear to balance one another should do so absolutely. If, for example, a scroll is reversed, the two sides of it should take identically the same curve, and any two corresponding flowers should be exactly on the same level. The main lines and more important features thus balancing one another, we may take what liberty we like with details which do not assert themselves; and it is always a charm in a design to find variations showing that the pattern has not been just traced and reversed; but it is the little difference in level, or the slight departure from the perpendicular, where the eye expects mechanical accuracy, that is in most cases responsible for unfortunate lines in repeated surface patterns.

If the repeat of your pattern is small, you naturally get all the variety you can into it, knowing that repetition will bring with it quite enough of order and formality; but if you have a large space to cover, it is as well always, unless you wish it to present an absolutely uniform appearance, to settle points in it which shall be marked so as to form, as it were, links between the inevitable points which recurrence will reveal in the design.

As for ornament which is not merely based on geometric lines, but consists of geometric forms, it is very easy to have too much of it. Its most satisfactory use is perhaps to be found in mosaic, to which it seems naturally adapted, more especially where the colours are varied in an accidental manner, as is the case with marble and wood. Such accidental variation is, in fact, exactly what is necessary to geometric work. The unexpectedness of the tints just counteracts the certainty of the forms, and redeems the effect from mere mechanism. The very reverse of this fit relation of form to colour is seen in the ordinary encaustic tile work, which seems somehow to be always harsh and common, even when the colours employed are not in themselves absolutely crude. At all events they are never sufficiently varied—perhaps it is not in the nature of the manufacture that there should be much variety; in which case the look-out is hopeless. Certain glazed Moorish tile work of this kind is not free from harshness and even crudity. Yet we see in Italian Giottesque decoration, which is mainly, so far as its ornamental detail is concerned, in imitation of the forms of geometric inlay, that even in flat-painted work the colour can be subdued to a key so admirably in accord with mechanical forms that, literally, the only fault to be found with it lies in its pretence. Perhaps the charm is largely due to the fact that the forms are not precisely mechanical, but put in with some freedom, and even with a sketchiness that would horrify the British workman. Time, too, has doubtless been kind. Still, there is the happy result, which is not without its lesson for us.

By the way, in the ornamental glass mosaic of GIOTTO's time we get the very perfection of relation between geometric form and glowing colour. Nothing like harshness of form is possible with these little facets of glass, which catch the light at all manner of angles, and glitter according to their own bright will.

Lines of a more or less geometric character are so useful in ornamental design that one is bound to avail oneself of them. But there is always a danger in using them, lest they should assert themselves unduly. What admirable use GROLIER, for example, made of them; yet there are many of his bindings in which they stand too emphatically pronounced.

One has noticed in many an instance of old stained glass and painted decoration the satisfactory result of a portion of the design being worn away, or nearly so, hinting to us that it is not absolutely necessary that geometric forms should stand confessed in all their naked severity. It is quite possible, and quite permissible, to subdue, if not to obliterate them here and there, so that the logical cohesion of the design exists, without the obvious stiffness which results from the preponderance of geometric forms.

There is a way of relieving the monotony of geometric design, used in Byzantine art (one sees it at Ravenna), by interspersing sprigs of very conventional foliage in the midst of interlaced strap work, which is very charming. But in Byzantine art this is scarcely necessary; so little mechanical are the forms that they are scarcely to be called geometric.

Some sort of geometric basis to a design gives scale, severity, and strength to it, so that, apart from any necessity there may be for repetition (which, of course, involves recurrence of the parts in geometric order), we habitually adopt it as an element almost indispensable in design.

The point to which geometric design has been carried by the Arabs is something really marvellous. Not so marvellous as it at first appears, for it seems at first as if human ingenuity could never so much as grasp the thread of such intricate pattern-work, much less invent it—yet still sufficiently bewildering, even when one is familiar with the, after all, simple lines on which it is constructed. But even in such work as this, where geometric design certainly reaches its zenith, one cannot escape a certain weariness of interlacing lines and parts repeated; and a certain amount of wear and tear, and even of dilapidation, is a relief to the eye. I have always found the greatest pleasure in examples that, whether by design or accident, are not altogether mechanical in execution.

This brings me to the conclusion which has pressed itself

upon my conviction, that it is the geometric distribution of ornament which is valuable, whilst geometric accuracy of execution is not merely worthless but fatal to ornament. Why is it that modern Gothic tracery is apt to be so hideously hard compared to the old examples from which it is copied? Simply that it is what the builder calls "true," which the old work is not, and probably never was. Even in old work, whose edges have been softened by time, what a relief it is to get away from the evidence of mechanism. In German geometric tracery one is conscious of the part played by the compasses in the design; and in English Perpendicular work there is always a suggestion of the T square; but in French Flamboyant forms one sees only the artist. There is a geometric relation of the parts, but the lines flow freely from the hand of the designer.

Great importance has sometimes been attached to the construction of ornament, not only on a geometric basis, but upon the principle of the multiplication of one simple unit throughout. It is quite true that a great deal of Arab and Moresque pattern work is reducible, for all its intricacy, to the simplest possible elements; and that star shapes, diamond forms, hexagons, and other polygons, are all multiples of the simple triangle upon which this particular variety of Eastern design appears to be built up. But I am not so certain that it is altogether a building process with the Oriental designer. When you come to deal with absolutely geometric shapes, the subdivision of such shapes into similar geometric divisions is almost a natural instinct, with anyone whose ingenuity lies at all in the direction of such art. The space to be ornamented suggests, in fact, its being broken up into segments of like shape. The square, for example, suggests a smaller square set anglewise within it, and the resulting triangles at the corners suggest, again, a triangle placed in the same way in its centre, dividing the space into four equal equilateral triangles. Whether, however, the design be the result of a process of multiplication or division of parts, matters little; except that too much stress has been laid, I think, upon this constructive form of design. No doubt the construction is there; and there is significance in the fact. But I fancy that the Mohammedan artists were not always thinking of the principle underlying their work, even if they were always conscious of it. Their art was traditional and instinctive to a degree. And, anyway, I disbelieve entirely in the advisability, and even in the possibility, of our designing on any such scientific principles as may doubtless be discovered in Alhambresque design. It is possible, very likely, mathematically to reconstruct the subtlest curves of Greek architecture; but does anyone imagine that they are the outcome of mathematical science? A scientist perhaps! I have heard such an one enthusiastic in the anticipation of a time when colour shall be reduced to a matter of mathematical certainty—in which case it will be about as interesting as a game of chess where, one move made, the rest follow as if the human machines engaged in it had been wound up. Art proceeds, happily, upon quite different lines. And though the results of art may be scientifically explained perhaps, the effects of art are not to be scientifically produced.

## STUDIOS IN ROME.—SENOR R. VILLEGAS'.

[BY A CORRESPONDENT.]

ALTHOUGH Rome includes the studios of many accomplished painters of various nationalities, it cannot be recommended as the best place for the education of a young artist, for the reason that most of the schools represented have assumed their final and completed condition and are not in a state of progress. They do not suggest advancement, but satisfaction with an acquired faculty; a resting in the present stage rather than an ambitious desire for new conquests, and the development of higher powers. In this respect the art condition of Rome differs from that of England; for we have there manifested from time to time perceptible evidences of a desire towards elevation and extension; and although this effort too often mistakes its proper object in the attempt to get a more bold literalism, to surpass in merely copying the forms of nature instead of seeking to express a creative individuality in the work done, it at least suggests to the student that something more remains to be attained beyond that which is accomplished. Perhaps it is this very quality of a want of finality—its not being frozen or crystallised, so to speak—that is the

most hopeful feature in English art, as it, indeed, constitutes one of its charms. It is a characteristic notable from early times. REYNOLDS and TURNER were constantly making experiments, both conceptional and manipulative. Their failures even are valuable, because they offer suggestions, break down the barriers of convention, introduce freedom of method, and illustrate new points of view. The kind of art, however, to which I purpose to call the reader's attention in this paper does not belong to this category. It is not experimental at all. As it is complete in itself, it suggests nothing further: as the desire and ambition of the manipulator are satisfied, it indicates nothing beyond itself. It is emphatically the art of the senses, appealing to the eye and to the taste rather than to the soul and the higher æsthetic faculties. A ROSSETTI or a WATTS would be as impossible in the modern art of the Latin races as a FORTUNY or a VILLEGAS would be in our own.\*

And yet, regarding the means of work, the executive ability which goes straight to its object of representation with its distinctive individuality of form, its sparkle, its glitter—those qualities which give special character to every object in a pictorial relationship—the southern schools certainly surpass those of the north. But then it is only the external character which is given: the "nothing more" but the "primrose." One holds no mental association with the objects thus represented. They appeal to the eye with surprising force, but somehow or other they seem to have no connection with the inward faculty. They touch no emotional link, they excite no profound sentiment. They are a wonder to the outward sense, but never penetrate the soul, never reach the region where they come to be an influential element of the mental and moral nature.

These remarks are illustrated in the works of one of the most deservedly famous artists of this school, Señor VILLEGAS, a Spanish painter established in Rome. We will pass some of his more important works specially under review.

The largest and most important picture at present in his studio (it measures 6 by 4 mètres) is taken from Venetian history. It is entitled "*The Triumph of Foscari*," and represents the ceremonial of his accession to the office of doge. He stands in the foreground clothed in the official robes. Behind is a group of senators. A canopy is held over his head. A procession of damsels, in the centre of which is his wife, descends the crimson-covered steps presumably to enter the bucentaur, or state barge, for the purpose of going through the ceremony of "marrying the sea." Trumpeters, attendants, ambassadors, and other official persons make up an imposing pageant, all rendered broadly and clearly in the diffused light of a clear atmosphere.

Another important work scarcely less in size is "*The Death of the Bull-fighter*." For this picture a number of preparatory studies have been made, and a smaller well-finished painting has been produced. The subject is a dramatic one. A bull-fighter, who has been worsted in the combat, is brought into the chapel attached to the arena. He is laid upon a bier in front of the altar, clothed in a white shirt, his feet covered with a scarlet cloak, his countenance fixed in the rigid pallors of death. A priest stands at his head, reading the office; a lighted candle is placed at his feet. A group of male figures stand around in various attitudes expressive of reverence, concern, or curiosity. They are said to be all of them portraits of celebrated bull-fighters. Written upon their countenances one seems to discern the physical and moral hardness of their trade. Two municipal guards in the background discuss the tragedy. At the left some servants of the ring carry the weapons and clothes of the victim. A glimpse of the sun-lighted arena is seen through the door of the chapel. The whole picture is conceived with the force of a reality, and could only have been painted by one familiar with the scene it portrays. The larger picture, which is barely laid in on an unprepared canvas, is a marvel of dexterous manipulation and robust grasp of the subject. The firm and spirited drawing of the figures, the masterly indication of the accessories, the textures and qualities of the various objects and garments, all bear witness to the vigorous ability of the artist.

Another striking and remarkable picture is that of a grave-digger in a cemetery studded with crosses and other symbols of the dead, digging a grave in the twilight of a summer's evening. One streak of orange light lies on the horizon at the

\* These remarks as well as some of those which follow, are, it is needless to say, only partially applicable to the works of the French School.

bottom of a grey sky ; fire-flies flit through the gloom. By the side of the grave an unclothed corpse lies imperfectly covered by a single sheet, wan and ghostly in the glimmering light. The grave-digger pauses from his work, turning to look at the procession of a well appointed funeral which comes along an adjacent alley of cypresses. The intention of the picture supposably lies in the contrast between the two modes of burial.

In the same grim category may be placed another of the works of this painter. It is entitled *The Last Kiss*. Two covered corpses lie at a doorway in a Turkish house or palace, near which is a pool of blood. A stained sword is laid across the corpses. A censer smokes in the foreground, a pair of slippers being left near it. Hung by the hair on the framework of a wrought-iron lamp a male and a female head are suspended, their ghastly lips meeting in the pale kiss of death.

Besides these we have a sketch of a Venetian fête on the Grand Canal ; an occasion with which most visitors to that city are acquainted. The gondolas are decked in foliage, suspended with coloured lamps. A round moon rises on the horizon. Another elaborated sketch gives us the interior of *Madrid Cathedral*, in which a baptism is taking place. It is painted with that mixture of lightness of touch and attention to detail which distinguishes the work of FORTUNY representing a ceremonial taking place in the same building.

M. VILLEGAS has also some fine examples in water-colour, though it is evident he does not choose this medium for the elaboration of his more complex fancies. One represents the doge, FOSCARI, having been compelled to condemn his own son to torture and banishment for the crime of murder, which it ultimately turned out he had not committed. The doge sits in the judgment chair, holding the arms of it with a spasmodic grasp as the council leaves his presence. The story is pathetically retold, by the way, in ROGERS' "Italy." Another very clever water-colour is the half-length figure of a Venetian advocate clothed in scarlet with a head-dress of the same colour, reading a document with a seal attached. His head is thrown back to catch the light, or that he may glance at the effect of his utterance upon his auditory. It is spirited and artistic in treatment.

Besides these we have a large number of minor sketches and studies, some of them small but all touched in with a rare facility. Most elaborate pieces of ornament or architecture are rendered with a justness of line and artistic sentiment of colour often little less than wonderful, in which the full play of the distinctive qualities of this school of painting are clearly seen. Figures whose movement and spirit appear to have flung themselves on the canvas or panel without an apparent effort, live under the touch and move in the freedom of life. The minutest detail seems to come as naturally as the general broad forms, and to be done with the greatest ease and certainty.

In the foregoing description of pictures the preponderance of ghastly subjects cannot fail to have struck the reader : the deliberate choice of circumstances of horror or crime. Why this should be the case with a people who have the reputation of being more light-hearted than ourselves it is hard to say. There are certainly no precedents for it in the earlier schools of Spain and Italy ; at least not as a ruling sentiment, and never at all in the best epochs. Is it that a conscious diminution of power in the higher regions of art, as an expression of the most elevated emotion, has induced the false substitute of exciting and catastrophic events for that lofty artistic faculty which naturally dealt in a grand manner even with unheroic themes ? or is it that a moral depreciation in regarding things has succeeded those noble schools ? However it be it is to be deplored. What can be the satisfaction to any healthily-constituted mind, to see these horrors continually served up before it in a world containing so much of what is beautiful and wholesome, morally and materially ; to have deliberate choice made of its most distressing or disgusting situations, and these set before us to give us pleasure ? Not here, certainly, does the path of that art lie which is to lead us to the regions of a higher education, which is to be to us some compensation for the disorders and confusions of life, which is to help us to escape from some of its most depressing conditions and circumstances, into the purer atmosphere of an existence worthy of men and women, whose pleasures lie in the exercise of other emotions than those excited by the charnel, the morgue, and the bloody sword of the executioner.

## AMERICAN BRICKMAKING.\*

THE brickmakers are able to claim a sufficiently remote origin for their craft, for indeed no one can say how early men began to build walls of slabs made of sun-dried clay. Even when it is asserted that TUBAL CAIN must have known where to obtain fire-bricks for his furnaces, who can show evidence to the contrary ? But old as the trade may be, there seems to be not the least probability that it will be allowed to become obsolete. Stone and wood, concrete and artificial stone, iron and glass, are all very well, but they cannot hold their place against brick. It has been so largely used of late years that one might be justified in predicting that the architecture of the future will be mainly expressed in brick. The least improvement in the production of so important a building material is therefore of almost universal interest, and we gladly welcome a book by an author who is an architect and a brickmaker, and in which American practice is described fully and frankly, just as if foreign competition did not exist. Mr. DAVIS is proud of the bricks which are produced in America, and if we may judge by the tests which have been applied to them, his pride is well founded. American terracotta is also of a high class. The manufacture of ornamental tiles is adapted to a country in which artistic skill exists, and who knows but we may shortly see, as Mr. DAVIS foretells, American tiles used in Staffordshire itself ? The Americans in their manufactures from clay are exercising the ingenuity which they have done so much with other materials, and it behoves our manufacturers to avoid underrating the efforts of such formidable rivals. Mr. DAVIS's book will enable them to understand how much progress has been made up to the present.

Brickmaking is one of those arts in which the chemist's knowledge is all-important. Mr. DAVIS maintains that physical tests and experiments are superior to chemical tests, but both kinds should be employed, for one is as essential as the other. The so-called physical testing is very often mere empiricism in its worst form. The difference between "fatness" and "poorness" in clays, which means so much to a brickmaker, is a chemical question, and so are other phenomena. We grant that chemistry is in some things not much of a guide. Why clay when freshly dug should make bad bricks, while clay from the same field, if dug in winter, well exposed to the weather, and turned over two or three times, should produce sound bricks, or why exposure to frost should, as it were, ripen the clay, are questions which an honest chemist must confess to be beyond him. But chemistry will help a man to ascertain whether there are iron pyrites in the clay, when he must expect (if he uses a high degree of heat) to see air-holes in his bricks, or vegetable matter, which will produce a similar result and a larger loss, or limestone pebbles, which mean unsound bricks and much grumbling from buyers. Clay is not always of one quality, and in such cases the bricks will not be fired equally ; chemistry enables us to take the necessary precautions. Mr. DAVIS evidently cares little for chemistry, and, if his book has a defect, it is the absence of analyses. Thus, for example, he tells us that the "best brick clays are composed of silica three-fifths, alumina one-fifth, and the remaining one-fifth of iron, lime, &c." We confess we were exceedingly surprised to find those constituents accepted as expressing the results of analyses in America, for precisely the same formula is to be found in Dr. URE's Dictionary, published a great many years ago. It is a sort of general rule or standard which does not represent all the brick clays of England, and we doubt if it is more true for the States. The Burham clay has only 43 per cent. of silica, and the London clay 49 per cent., neither being equal to three-fifths of the whole mass.

If we had analyses, they might enable us to understand the remarkable strength which is ascribed to American bricks. In MAHAN'S "Civil Engineering," an American book which at one time was used as an authority in England, we are told that a good brick required a weight of 1,200 lbs. per square inch to crush it. Mr. DAVIS says that good bricks, especially those which are specified for public buildings, should be capable of withstanding a pressure of 7,000 lbs. per square inch. The strength of twelve samples which were tested by Major-General MEIGS, for a contract for a public building now in course of erection at Washington, varied from 5,960 lbs. to 10,290 lbs. This is an enormous increase from MAHAN'S time, and,

\* A Practical Treatise on the Manufacture of Bricks, Tiles, Terracotta, &c. By Charles Thomas Davis. Philadelphia : Baird & Co. London : Sampson Low & Co.

assuming the figures in both cases to be correct, is even more remarkable than the improvement which has taken place in the quality of English Portland cement, under the tests of the Metropolitan Board of Works. But how do the figures compare with those relating to English bricks? Mr. GRANT, who superintended the tests for the Board, does not appear to have found an English brick to bear more than a ton, or 2,240 lbs. per square inch, and some are registered as being crushed with 716 lbs. per inch. In the careful experiments which were made in connection with the Britannia Bridge the mean crushing strength was found to be only 521 lbs. When it is remembered that the great piers in St. Paul's Cathedral have not to sustain more than 130 lbs. per square inch, the English bricks appear to be of ample strength. Mr. DAVIS acknowledges that "no bricks have ever before made so good a showing" as those for the Washington contract; and the difference between them and other samples is so great, it is a pity that some information is not given about the testing apparatus which Major-General MEIGS employed.

By an Act passed in 1802 the size of bricks was prescribed, and although deviation from the normal size is no longer penal, the majority of English bricks are of uniform dimensions. American bricks vary in size, and "often there is a diversity in the same location, the measurements for common bricks running from  $7\frac{1}{2}$  to  $9\frac{1}{4}$  inches in length,  $3\frac{1}{2}$  to  $4\frac{1}{2}$  in width, and from 2 to  $2\frac{1}{4}$  in thickness, which variation is largely owing to the nature of the clay employed." The moulds used for hand-made bricks lose their shape, and in consequence bricks made at the close of the year are thinner than those made in the spring. In order to save the public from the loss that would follow the use of attenuated bricks, there is a by-law in Washington by which, under a penalty of twenty-five dollars, all moulds must be stamped by the inspector of weights and measures; the moulds for plain bricks being  $9\frac{1}{4}$  by  $4\frac{1}{2}$  by  $2\frac{1}{4}$  inches, and for stocks  $2\frac{5}{8}$  inches clear. If the American bricks are smaller, it is claimed for them that they are stronger and of better quality than those made in England.

Mr. CARLYLE used to be very severe on London bricks, which he maintained could last no more than sixty years, instead of the six thousand years which should be the term of a brick's life. Mr. DAVIS says that bad as English bricks are in general, those made in London are the weakest, partly owing to the nature of the clay, but mainly from the breeze which is mixed with the clay. It is often supposed that breeze only helps as a fuel to fire the clay, but it can also be employed to serve instead of sand at a much less cost, and it prevents shrinking. Mr. DAVIS says that "clay is the only material of which bricks should be made," and if the Washington bricks are simply of clay they form an argument in support of his theory. But in England, and also on the continent of Europe, clay alone is not supposed to make good bricks; there must be some additional material that corresponds with an alloy for a metal.

We have not space to notice the parts in Mr. DAVIS's book which treat of terra-cotta, tiles, and other fictile works. In them he also represents the American spirit, and there is rather much of the "high falutin" tone. But in advocating the principle that a piece of terra-cotta or a tile should depend for its value upon the quality of the art it expresses rather than the reputation of the pottery, we are in entire accordance with him. There is art work produced in America which can compare with what is done in France as well as in England, and, in fact, the Continental system is adopted in the States; and artists who have been successful in painting gallery pictures and in sculpture have willingly undertaken commissions from manufacturers for designs. The general ambition in the States is for the workman to become a master, and Mr. DAVIS is an advocate for the principle that an artist should possess a share in the business which he has helped to create or extend. According to a French thinker, much fewer thoughts in a writer would be condemned if we endeavoured to conceive them like the author, and, by putting oneself in the position of an American reader, Mr. DAVIS's book will appear to have few shortcomings. That it occasionally shows a want of respect for English practice must be admitted, but, on the other hand, the book tells the reader more about the processes employed in brickmaking and the allied crafts than is to be found in any book published in this country.

**The Luxembourg Museum** was closed on Monday in order that the pictures purchased by the State at the Salon exhibition may be hung. It will reopen on the 15th inst.

## THE BERLIN MUSEUMS.

A LETTER has appeared from Mr. John Leighton, F.S.A., in which he writes:—Hitherto Berlin has not been to the fore in matters of art, nor, indeed, has it been the art capital of Germany. Now it is awakening to a sense of the importance of art culture, not alone in painting and sculpture pure and simple, but to the development of those arts as applied to home dwellings and the necessities of daily life. The old museums are being enlarged, while the Kunst-Gewerbe Museum (evidently a copy of our own at South Kensington), though hardly occupied, sees another still larger rising beside it. In the Beuth-Schinkel Museum they have now arranged the Hamilton books and the Botticelli drawings, which will soon be on view.

This German metropolis is particularly rich in samples of early Italian art, and one cannot but admire the solicitude of the new Empire to enrich its capital. The Schliemann acquisitions from Troy are now perfectly arranged, though in art influence they are of small importance beside the magnificent marbles recently recovered from the Acropolis of Pergamos in Asia Minor. These works, though they may be wanting in classic purity as compared with those of the Parthenon in the British Museum, evince a vigour of picturesque treatment surpassed by none. They are colossal in size and formed the bas-reliefs to the altar enclosure of the Temple of Jupiter, representing, as they do, the triumph of Zeus and Athene over giants and monsters. These works were known to us, some fragments from the same place being now in Bloomsbury; and it is not much to our credit that we should have allowed such an enduring attraction to have become the property of another nation more on the alert than we. The greater part of the fragments lie like huge mosaics on the floor of an immense gallery in two long lines, and at present have to be viewed from above, though four of the most complete sections are now set up under the dome in the vestibule for the purpose of being photographed; and I would strongly advise our sculptors to acquire a copy of these works (circ. 180 B.C.), as they develop a richness of fancy, knowledge of form, and grandeur of execution found in no other works on so large a scale. The flow of line action and treatment of drapery is marvellous. Unfortunately, many parts are missing, though the perfect state of much is astonishing, showing the work of various hands governed by one master mind.

In Berlin, upon the space between the cathedral and the national museum, I believe it is the intention of the emperor to build a Campo Santo. The ground is at present occupied by a temporary erection containing full-sized copies of the gables of the ends of the Temple of Olympia, with plans, photographs, and restorations of the same; also the *Nike* of Pionios and the *Hermes* of Praxiteles, as restored by Schaper. This latter is one of the few divine statues of the world, owing its preservation entirely to having fallen upon mud, where it rested until discovered in 1877. I am told that diplomacy here has exercised great pressure and temptation upon Greece to induce the ruler of the Hellenes to part with the original, hitherto in vain, King George having stronger relationship with Russia than Germany.

## THE HERKOMER ART SCHOOL.

THE first session of the Herkomer Art School has come to a close, and so great has been its success that the President is sanguine enough to predict that if it goes on as it has done it will in five years be the leading art school in Europe. The personal aspect of things works so well, the individuality of each student has been so prominent and sustained, and the special criticism addressed to each one according to need before the whole class has succeeded so well, that no results of work such as has been executed by the students at Bushey are to be found in any other art school. At South Kensington especially, the laborious striving after the perfection of mere detail is persevered in at the expense of the spirit of a subject. One of Mr. Herkomer's first objects was to bring the students to realise what was "artistic;" they had no difficulty in seeing when things were right, correct, and measured, but the ladies especially were a long time coming to the true sense of what art means. Bold, daring work was encouraged, and little personalities, if not abnormally mannered, were not suppressed. The wide latitude thus conceded produced some striking work, and of so varied a character that Mr. Herkomer himself sometimes could not tell whose study was before him. Another noteworthy fact is that a few strong students have established a type of work which the others have to a certain extent followed. There has been no trifling; all the students have worked remarkably hard, and all at times have been utterly depressed and downcast about their work; more so, their President believes than in any other body of art students. In every case the depression has borne good fruit, for no effort has been spared to reach the ideal vaguely hovering before them. The first difficulties arose from the peculiar light of the studios. It was of so subtle a character that the first month was disastrous to all alike; but, encouraged by the assertion that if they could

paint in that light they could in any, the students persevered, and most now succeed in all but the triangular room, where the figure is painted entirely surrounded by light. This has been christened the "torture" room, because of its susceptibility to all the variations of daylight as the earth changes its position with regard to the sun. Very little landscape work has been done, in the belief that if the facility to paint everything in the way of figures were acquired it would be comparatively easy to paint anything else. Several students, on the other hand, have learnt all the processes of etching, and have produced their own designs in Mr. Herkomer's workshop. Of work of this class the public will perhaps be able to judge in the ensuing session; for if sufficient good designs are forthcoming, they will be published in folio form and sold for the benefit of the students. Some designs were sent in this year; but the students, although a few sent really excellent subjects, were for the most part too young for the effort. All other work will, however, be kept strictly private; no studies will ever be shown, and no rewards or prizes offered, the aim being to work for love of art simply. Except in some small matters of order, no alterations will be made; the original scheme will be pursued without any modifications whatever. There has been no difficulty in enforcing the rules. Severe as they were, they have never been broken; every effort has been made by the students to keep up to time and work conscientiously every day. Mr. Herkomer speaks with much satisfaction and admiration not only of the results in this direction, but also of the courteous, frank, and kindly behaviour of the students one towards another. With fifteen gentlemen and nineteen ladies it would not have been unreasonable to expect some two or three to flirt, to quarrel, or be snobbish. But nothing has occurred to break the peace of the small art community, and no complaint of any kind is made against any one of the thirty-four. Their intercourse one with another has been of the most genial character: musical evenings, tea parties, and picnics have been given amongst the students, a reading-room of current literature and a library of reference have been formed, and each Saturday Mr. Herkomer, throwing off the master, cordially invited all the students to dine and spend the evening with him. The first night the "Meistersinger" was produced Mr. Herkomer took seats for them at the opera; in the winter he obtained free passes for them to the chief art exhibitions; and in the summer they have had lawn tennis as a recreation after their hard work.

The next session, which commences October 6, will see not a few of the old students back; the weeding out which Mr. Herkomer reserved for his discretion has not been very great. Some have left because they themselves felt unable to continue; others to study by themselves, the school being no longer enough for them; whilst of those who remain, some, Mr. Herkomer considers, have not had sufficient chance, being of slower development than the others; and some, again, return at their own wish. The school will never be a large one. The original maximum of sixty has even now been curtailed to fifty, and it is probable that just as Mr. Herkomer only accepted some thirty students to start with, he will not take the full number for another year or two. The specimen gallery, which was to be a special feature of the school, has, thanks to the generous response of living artists, been well supplied throughout the year.

## MR. SHAW-LEFEVRE ON THE RESTORATION OF WESTMINSTER HALL.

ON Tuesday Mr. Shaw-Lefevre, First Commissioner of Works, invited a party of ladies and gentlemen to Westminster, when (in the absence of Mr. Pearson) he explained the proposed restoration. Mr. Shaw-Lefevre spoke as follows:—

When the buildings of the old law courts were demolished, and the front of Westminster Hall, with its flying buttresses, was for the first time exposed, I had no idea that any such works as are now contemplated by Mr. Pearson would be necessary. All that I contemplated was a repair and a restoration of the walls of the building and of the flying buttresses, and possibly also a lengthening of the existing windows of the hall. It was at once apparent that these windows are not of good proportion; they are very short—they are, indeed, much shorter than the windows on the east side of the hall—and it occurred to me, and to most people who looked casually at the building, that when the law courts were built, at the commencement of this century, the windows on this side must have been shortened in order to enable the law courts to be erected close to the hall. With a view, then, to effect the necessary restorations, and possibly to lower the sills of these windows so as to make them of better proportions, I requested Mr. Pearson, than whom there is certainly no architect in the country better qualified, whether from his great experience in such cases, his great knowledge of Gothic architecture, and his well-known tenderness in dealing with restorations, to investigate the subject. He has during the last few months made a most laborious research into the history of the hall from all the records and prints that are to be found of it, and has excavated all the foundations

of the buildings formerly annexed to it. These researches have brought to light many most interesting facts connected with the hall. It is now certain that all the lower part of the wall nearly up to the sills of the windows, and including the flat buttresses standing against the wall, are exactly in the state in which they were built by William Rufus. The marks of the chisel are still to be seen on this wall and on these buttresses. The perfect condition of this old Norman masonry is due to the fact that from a very early time it was completely covered and secured from damage by a cloister which ran along the whole length of the hall. This was erected by Richard II. In his time the present noble roof was erected; the flying buttresses were also built in order to give support to the roof. The upper part of the wall was completely remodelled. It was refaced with new stone, and the present windows were inserted. At the same time, he undoubtedly erected a double-storeyed cloister under the flying buttresses and against the wall of the hall. The foundations of the wall of this cloister have been laid bare along the whole length of the hall between the buttresses. Its roof and the floor of the upper storey were supported by arches springing from the Norman buttresses against the wall so as to avoid throwing the weight of them on the wall of the hall itself. You will see the indication of both tiers of arches in every bay between the buttresses, in some more perfect than in others. It is quite certain, therefore, that a double cloister existed here from the time of Richard II. till the beginning of this century, when Sir John Soane erected the law courts. There are also existing plans made by Sir Christopher Wren showing how the upper floor of the cloister was divided into rooms. They were approached by stairs in the hall itself and also by a staircase outside the hall. There is no plan existing showing how the lower storey was laid out. It, perhaps, consisted of cellars with open arches, as Mr. Pearson thinks, or, perhaps, of a long gallery; but of the existence of this double-storeyed cloister there cannot be the smallest doubt. Its roof cut across the flying buttresses, and the corbels of the flying buttresses were in the rooms of the upper storey, just as in the case of Westminster Abbey the corbels of the buttresses are to be found in the chapels of the side aisles. The walls in this upper storey were painted, and Mr. Pearson states that in wet weather the traces of paint are still visible. As I have already said, the existence of this cloister preserved the Norman walls down to the present time, and the existence of this cloister also accounts for the windows above it being so short. The lower part of these windows must have been cut off from view by the wall of the cloister except at a distance; the buttresses stood out at least 8 feet beyond the wall, and the flying buttresses must have been visible above the cloister. At the north end of the cloister and at right angles to the hall you will see the foundations of a building of about 60 feet in length and 30 feet in depth fronting New Palace Yard. This building, erected originally in Richard II.'s time, was replaced later by a Tudor building, the upper part of which was used as a residence by Queen Elizabeth, and later as the Great Hall of Exchequer, while the rooms in the upper part of the cloister were used as private rooms by the judges when the courts sat in Westminster Hall itself. This, then, being the actual condition of the hall, the question naturally arises what should be done with it. Two alternatives only, I think, present themselves—the one is to patch up the wall and the buttresses, leaving the west front very much as it is; the other is to rebuild the cloister as nearly as possible as it existed from the time of Richard II. to the present century. If the first course be adopted, it would be necessary to recase the whole of the lower part of the wall—the old Norman work of William Rufus—with fresh stone, as the existing stone will not bear exposure and will certainly perish. All the remains of the arches which I have spoken of will also disappear. I venture to think that such a course would be most unwise. It would be an act almost of Vandalism. We should lose almost the only existing piece of stone-work of Norman times in the metropolis. I doubt whether any responsible architect could be found who would advise such a course or who would undertake to carry it out. The hall also thus dealt with would not look well. The windows, as I have pointed out, are not in good proportions, and the buttresses standing out as mere supports to the wall of the hall would be unsightly. There is scarcely any precedent for flying buttresses in this condition; as a general rule they are intended to enclose between them and the wall or roof they support some side aisle or cloister. The other alternative is, as I have said, to rebuild the two-storeyed cloister in the form, as near as possible, in which it originally existed. The advantage of this will be that it will act as a protection to the Norman wall behind it, which can then be left uncovered and always open to view. It will also, in the opinion of those much better qualified to judge than myself, add great dignity to the hall. There will be two rows of windows, and a double set of battlements, and the lower storey of the cloisters will be lighted by open arches with grates. Now the main objection to all this is that the hall itself even thus restored will not be an effective object in the general view of the building; that it was never intended to be exposed to view, and that it ought to be surrounded by other buildings as it was in olden times—and those who hold this view consider that it would be better to complete Sir Charles Barry's original intention of building a new wing from St. Stephen's Porch

parallel with and in front of the hall, to join another wing from the Clock Tower. In the first place I would reply to this that such a work would cost at least 300,000*l*. It is not, as far as I know, wanted for the accommodation of the House. All idea of making this addition was long ago definitively abandoned. As the front of it would extend beyond the line of the roadway, it would narrow very inconveniently the road between the Houses of Parliament and St. Margaret's Church, and further it would not solve the question what should be done for the restoration of the front of Westminster Hall. The hall would be hidden behind this wing, but it would still be exposed to view in a court-yard, and it would be necessary to do something with it. What we now propose to do is not inconsistent with the addition of the wing, if at some time hereafter it should be thought desirable to add largely to the buildings. Lastly, I myself think that on the score of dignity of the building, and the general beauty of the group, it would be far better to leave the hall exposed, but restored as now proposed. Sir Charles Barry's building, as a whole, is a noble and beautiful one; but my belief is that if these wings were completed the effect would not be good. There would be monotony in the endless reiteration of the same elaborate detail. The great hall with its high pitched roof and massive walls is, I think, a great relief to the eye and a break in the monotony of the building. When the whole building is seen from the other side of Parliament Square, Westminster Hall when restored as it is proposed will form, with Sir Charles Barry's ornate buildings and beautiful towers, and with the Abbey, the most interesting and beautiful group of buildings to be found in Europe. This, however, is a matter of taste which it is difficult to argue. Another of Mr. Pearson's proposals is to raise two towers on the north side of the hall. The existing towers are completely dwarfed by Barry's building, which rises above them; and Sir Charles Barry himself contemplated raising these towers. This, however, is a work which will not be undertaken at present, and the consideration of it will stand over for another year. There remains only to consider the cost of the proposed works. The total cost is about 35,000*l*; of this 5,000*l*. is the cost of completing the side of St. Stephen's Porch on the plans of Sir Charles Barry; 8,000*l*. is the cost of raising the two towers; 7,000*l*. is the cost of repairing the wall and buttresses of the hall—the lower parts of the buttresses must be rebuilt—and 14,000*l*. is the cost of building the cloister and the building at right angles to the hall. On this arm we shall have two long galleries, 200 feet long by 20 feet, the lower one of which may either be used as an access for carriages to the hall or may be broken up into rooms opening into the hall. The upper gallery may be broken up into rooms. There will also be a noble room, 60 feet by 30 feet, which would be used for grand committees; and below there will be a standing place for horses in lieu of the present shed. This expenditure of 14,000*l*. is the only debatable point at present, and I do not think the total sum required is large for completing in a worthy and dignified manner the west front of this hall. As the wall of the hall was much injured by exposure to the weather in the past winter, I hope to be allowed to take a vote at once for this, so as to commence the work at once.

## EDUCATION, SCIENCE, AND ART.

THE Select Committee of the House of Commons appointed to consider how the Ministerial responsibility under which the votes for Education, Science, and Art are administered may be best secured have agreed to the following report:—

Your Committee have examined the present and several former Presidents and Vice-Presidents of the Council, Secretaries to the Lord Lieutenant of Ireland, permanent heads of the Education Department in London, the present Resident Commissioner of National Education in Ireland, and also other gentlemen conversant with the matters referred to your Committee. They have also considered the evidence taken before the Select Committee appointed in 1865 and 1866 to inquire into the constitution of the Committee of Council on Education.

The first question considered by your Committee was whether primary education in Great Britain and in Ireland should be placed under one supervising Minister. Your Committee are satisfied that under present circumstances it would be undesirable to disturb the existing arrangements as to the Ministerial responsibility for primary education in Ireland. They are also of opinion that primary education in England and Scotland should be under the control of the same Minister.

The Lord President of the Council, almost always a peer, is nominally the head of the Education Department for Great Britain. The Vice-President represents the department in the House of Commons, and really transacts almost all the business requiring authority above that of the permanent officials. Your Committee are of opinion that this arrangement is neither logical nor convenient. They see no sufficient reason why there should be any more real connection between the Education Department and the Privy Council than between the Board of Trade and the Privy Council; but as it may be convenient that the Minister for Educa-

tion should have occasionally the assistance, whether as to English or Scotch education, of other Privy Councillors specially summoned for consultation with him, they recommend that a Board of (or Committee of Council for) Education should be constituted under a President, who should be the real as well as nominal Minister, in this respect holding a position like that of the President of the Board of Trade. Hitherto there has been a separate Scotch Department of the Privy Council, and your Committee consider that it would be well to have a distinct permanent secretary appointed for Scotland, responsible to the Minister of Education.

Whether the Minister of Education should always be a member of the Cabinet or of the House of Commons, and what should be his salary, are questions upon which it is hardly within the province of your Committee to make absolute recommendations. They think, however, that the duties of this Minister should be recognised as not less important than those of some of the Secretaries of State. The Minister of Education should have the assistance of a Parliamentary Secretary, able to sit in either House of Parliament.

While on the whole preferring the plan they have suggested, your Committee do not deny that there are objections to the constitution of an administrative department in the form of a board which has no real existence. The permanent secretary and his assistants bind by their signature, nominally the board, really, the political chief. This system, it must be admitted, tends to lessen the direct control and responsibility to Parliament and the public which is apparent in the office of a Secretary of State.

The second question discussed by your Committee was whether, and if so what, authority should be exercised by the Minister of Education over endowed schools. Your Committee recommend that when schemes for endowed schools, whether in England or in Scotland, have come into operation, the Minister of Education should have full authority to call on the governing bodies to furnish him with such reports and information as he may require, and to direct any inquiries or inspection to be made which he may deem necessary.

As to public schools, your Committee recommend that the Minister of Education should be authorised to call for such reports and information as he may require from the governing bodies, but they are not of opinion that his powers should extend to directing inspection. With respect to the Universities in Great Britain receiving grants charged on the votes of Parliament or on the Consolidated Fund, the Minister should be authorised to require from them an annual report in such form as he may order. Your Committee have not taken any evidence as to reformatory and industrial schools, considering that these have so recently formed the subject of an inquiry by a Royal Commission, the report and recommendations of which are before Parliament. They see no reason for altering the present responsibility for workhouse schools or for the primary schools connected with the Army, the Navy, or the Marines. The responsibility for the administration of the votes for military and naval colleges does not appear to come within the reference to your Committee.

Your Committee see no reason to disturb the existing arrangements as to the supervision of the Science and Art Department.

There are various miscellaneous votes for science and art, such as those for scientific research distributed through the Royal Society, votes for meteorology, and votes in aid of the Royal Society of Edinburgh and the Royal Irish Academy. These votes, your Committee think, should be moved by the Minister of Education, and reports, when necessary, should be made to him.

Your Committee do not propose to bring the British Museum and the National Gallery into closer relations with Her Majesty's Government than those now existing, with this exception, that, in their opinion, the Minister of Education and the Parliamentary secretary should be *ex officio* trustees of each of those institutions. The President of the Council, your Committee notice, is now an *ex officio* trustee of the British Museum. The House of Commons would then look to the Education Department for explanations when the votes for the British Museum and the National Gallery are discussed in Committee of Supply.

The Committee, of which the Chancellor of the Exchequer was chairman, included, among other members, Sir J. Lubbock, Mr. Salt, Mr. Raikes, Sir L. Playfair, Mr. S. Morley, Mr. Pell, Mr. Sclater-Booth, and Mr. J. Collings.

**The Krupp Foundry at Essen** in 1860 had 1,764 workmen, but that number had risen to 7,084 ten years later, and it is now upwards of 20,000. Counting the women and children, Herr Krupp's establishment gives employment to 65,381 persons, of whom 29,000 live in houses belonging to their employer. The foundry is divided into eight sections, and there are 11 blast furnaces, 1,542 other furnaces, 439 steam boilers, 82 steam hammers, and 450 steam engines representing 185,000 horse power. At Essen alone, to say nothing of the branch establishments, there are nearly 40 miles of rails, 28 locomotives, 883 trucks, 69 horses, 191 wagons, 40 miles of telegraph wires, 35 telegraph stations, and 55 Morse instruments.

## NOTES AND COMMENTS.

SIR GEORGE CAMPBELL asked, on Monday last, the First Lord of the Treasury whether he would use his influence with the First Commissioner of Works to induce him to reserve for grand committee rooms and other extensions the ground to the west of Westminster Hall lately occupied by the law courts, so that the hall might be again, as it was originally, the centre of the Palace of Westminster. It is most desirable that this question now in debate should be put on its right basis, and it is historically absurd to suppose that the hall was built as a centre to numerous apartments. On the contrary, WILLIAM RUFUS, finding St. Edward's Hall too small to entertain the numerous followers of his father and their descendants, added the great hall to the palace, the kitchen being probably on the site of St. Mary de Crypt, the main body of the palace being to the south of this. WILLIAM RUFUS's hall had two rows of pillars and arches running the whole length, and consequently had a triple roof, like that of the choir of the Temple Church, and, therefore, the building was lighted by windows on both sides. This roof was probably destroyed by the great fire in circa 1370. To restore the hall RICHARD II.'s architect conceived the grand idea of the present magnificent single roof, and cleared away the pillars and arches of the old roof, not for the purpose of a Parliament House, for, from the time of HENRY III., Parliament met in the Chapter House of the Abbey, and that the palace extended to the south is shown by the existing Jewel Tower. Additions to the north of the hall, and some low buildings to the west, were added afterwards in the times of HENRY VII., HENRY VIII., and of ELIZABETH. The building of the cloisters of St. Mary de Crypt, and of St. Stephen's, one above the other, and the Bell Tower, darkened the hall and made the alterations by RICHARD necessary. RICHARD kept to the floor level of RUFUS, and thus from the silting up of the river boats at high tides were rowed up and down the hall within the memory of man. This latter fact is a point deserving consideration at a time when it is contemplated to build a cloister with steps *up* into the hall.

MR. PEARSON, R.A., has asked us to state that in the articles on his proposed restoration of Westminster Hall it was not quite correct to say, "Mr. PEARSON does not, in his proposed parapet, restore its details, nor even replace it on the same position or at the same level." Mr. PEARSON says it is not his intention to deviate from the lines imposed by the old remains where such exist.

LAST year the Manchester Ship Canal Bill passed the House of Commons, but was rejected by the Lords. This year the relations of the two Houses to the Bill were reversed, but in both cases an enormous sum of money has been wasted. That the promoters will persevere may be assumed as certain, for Manchester men are not to be daunted by a couple of defeats. The opponents of the scheme in Liverpool have admitted that there is no objection to that part of the scheme which deals with the district between Runcorn and Manchester, and the engineers can, without much difficulty, devise plans which will obviate injurious interference with the estuary of the Mersey. It is not denied that with a ship canal the saving in the cost of transit in the cotton trade would at least amount to half a million, and with so large a gain in view, the Committee will be justified in again lodging these plans with Parliament. The struggle is great, and has been carried on most creditably on both sides.

WHATEVER may be thought of Mr. PERRY's theories on sculpture, he merits unstinted praise for his perseverance in urging the South Kensington authorities to form a gallery of casts of Greek works. The gallery is now open to the public, although some of the examples are not in their places. Altogether there are about two hundred and fifty works, and they are suggestive of the growth and decline of Greek sculpture. Probably no two experts would agree about the choice of examples to illustrate the history of the art; but there are certain works which are as it were landmarks in that history, and copies of them are in the gallery. The Lion Gate at Mycenæ, the Branchidæ figures, the metopes of Selinus, the STRANGFORD Apollo, the group of Harmodios and Aristogeiton, the Ægina pediments, the Parthenon sculptures, the Mausoleum

at Halikarnassos, the Venus of Melos, the Dying Gaul, the Spinario, the Lateran Sophocles, the Ludovisi Juno, the Vatican Augustus, the Antinous, and the Roman portrait busts are among those works. The originals of some of them are in the British Museum, but others are found scattered through Europe, and even the travelled student will admit the advantage of having so many representative works collected in one gallery. The public, it is to be hoped, will take advantage of so great a boon. When the Sydenham Palace was founded, great expense was undergone to secure copies of famous statues, but they were never appreciated. The visitors preferred clowns, niggers, and dancing dogs to the best works of PHIDIAS. Times have altered, and we trust the South Kensington collection may have a happier fate. A useful handbook to the gallery has been compiled by Mr. PERRY.

THE Office of Works has lost no time in informing Messrs. LEEMING & LEEMING that, subject to the approval of Parliament, they will be appointed as architects for the new Admiralty and War Office. In the meantime the architects are to be placed in communication with the Office of Works, in order that such modifications and improvements in the plans as shall be suggested may be carried out. If the officials have a clear notion of what is best, it would have been wiser if it had been embodied in a sketch plan for the use of the competitors. It has not been announced what the Commander-in-Chief thinks of the various plans which are hung in Spring Gardens, although that opinion must be invaluable.

It has been stated that an Oxford scholar proposes to publish the best English renderings of the so-called poems of SAPPHO. He will find great difficulty in discovering a translation of the "Hymn to Venus" which will bear comparison with one by Mr. MARTIN MACDERMOTT, an architect now living in London, which was published many years ago in the *Cork Magazine*. It is a poet's version, without any of the stiffness and unreality which characterise the majority of versions of the shorter Greek and Latin poems.

WE have received several inquiries respecting the date for which plans must be sent in for the Amsterdam Competition. The particulars may be interpreted as stating that four months from May, or about the end of September, is the time given; but we have been informed on good authority that the competitors have until the end of October. Copies of the conditions, with a plan of the site, may be obtained by applying through the post to the Town Clerk, Amsterdam. A letter written in English will suffice. The Corporation are anxious to have a good international competition, but they seem to be of opinion that all the world takes an interest in the affairs of Amsterdam, and accordingly the competition runs the risk of being confined to a few architects.

FOR this year's examination at the City and Guilds of London Institute the subject of carpentry and joinery was added for the first time. Three hundred and sixty-nine candidates were examined, and of that number one hundred and twenty-five passed. Mr. W. W. Pocock, F.R.I.B.A., the Master of the Carpenters' Company, was the examiner, and states that, "as a whole, the papers were very creditable." But two hundred and forty-four failures, or sixty-six per cent. of the whole, are somewhat disheartening. The honours examination in carpentry and joinery for 1884-85 will consist of three parts:—(1) Advanced questions on the syllabus; (2) technical drawing; (3) the designing and executing during the year preceding the examination of an original piece of work, to be forwarded to London, together with drawings and particulars of quantity and quality of materials used. The last test is the most important, but without the influence of local trade societies we doubt if many carpenters will undertake the expense that is necessary.

MR. G. W. HASTINGS, M.P., has given notice that he will reintroduce his Bill to amend and consolidate the law of copyright in works of fine art and in photographs, and for representing the commission of fraud in the production and sale of such work, on the first day of next year's session of Parliament. It will be in the identical form of the Bill which was not successful in reaching a second reading during the present session. The delay is to be regretted, as the clauses had been revised throughout under instructions from Mr. BASIL FIELD.

## ILLUSTRATIONS.

PROMETHEUS BOUND.

THE picture from which this illustration is taken measures about 10 feet by 12 feet, and is one of those academic works in which, despite all the changes of taste, French connoisseurs can take pleasure. But it would be an error to suppose that the author confines himself to classical subjects. M. MAILLART has gained repute by portraits, pictures of every-day life, Scripture scenes, historical paintings, and designs for tapestry, as well as by his skill and learning as a professor. The scene which is depicted will be at once recognised as representing the opening scene in the *Prometheus Bound* of ÆSCHYLUS. As a punishment for having stolen fire from heaven and taught the rudiments of the arts to men, PROMETHEUS was chained to a cliff somewhere on the Caucasus. He was brought there by Strength and Force, who compelled HEPHÆSTUS or VULCAN to carry out the commands of ZEUS. But the smith is unwilling to affix bonds to the "high-minded son of THEMIS," which are to endure for thirty thousand years, and the following dialogue is heard:—

STR.—Well, well! why dost thou linger? why indulge  
In useless pity? Why not rather hate  
The god to gods most odious, who betrayed  
Thy bright prerogative to human kind?  
HEPH.—Of mighty influence is the conjunct tie  
Of kindred and familiar intercourse.  
STR.—Agreed, but how to disobey the sire?  
Does not this fear exceed that influence?  
HEPH.—Ruthless and reckless hast thou ever been.  
STR.—Wailing can't heal him; weary not thyself  
With idle and unprofitable grief.  
HEPH.—Out on my craft—my hateful handicraft!  
STR.—Why dost thou hate it? In good truth thy art  
Is wholly guiltless of thy present grief.  
HEPH.—Would that some other had it for his lot!  
STR.—Gods have done all they will, except the will  
To have the rule; for none is free but Zeus.  
HEPH.—I know it, and have nothing to gainsay.  
STR.—Wilt thou not hasten then to fetter him,  
Lest the dread sire behold thee loitering?  
HEPH.—The manacles are ready.  
STR.—With thy mallet  
Drive, clench them on him, bolt them to the rock.

It is sometimes supposed that Strength and Force are sons of STYX. M. MAILLART, with a purer appreciation of poetry, shows them to be goddesses, who are merciless as the Parcæ or Fates. Probably there would be no error in imagining that the picture is emblematic, and that the crowned Strength is a type of Germany, the conquered but unfaltering PROMETHEUS being a type of France.

## DESIGN FOR NEW ADMIRALTY AND WAR OFFICES.

WE publish reproductions of two more of Messrs. GLOVER & SALTER's geometrical drawings.

Arrangements had been made to publish some of the perspectives in this week's number of *The Architect*, but as the plates were not considered to do justice to the original views we were compelled to reject them. Our subscribers will find that there is an advantage in deferring the publication of the designs for a short time.

## HOUSES, LONG DITTON, SURREY.

THE two houses shown in the illustration were lately erected from the designs of Mr. J. NIXON HORSFIELD, architect.

## TECHNICAL EDUCATION.

A PAPER on this subject was read by Professor Garnett, of Nottingham, at the International Conference on Education, which was held at South Kensington on Tuesday. The author maintained that all technical teaching should commence in an attempt to teach the student to understand and to reason upon what he saw. Froebel's system laid a solid foundation for this in the infant school, trained the child's eye to form, his fingers to learn mechanical dexterity, and to master the elementary principles of design. At a later period the "object lesson" would call forth his reflective powers, his powers of observation, and any inventive faculties he might possess. Then the lessons of measurement should be taught, and after these had been acquired the elements of mechanics should be introduced. The speaker passed

through the various stages of technical teaching gained in his experience in Nottingham, where technical instruction has borne good fruit for the town directly and for the country in general. He held that there was one other feature which should form an important part of every provincial technical school—namely, a museum. This should comprise a collection of kinematic models, as well as of models and specimens illustrating applied mechanics, including the strength of materials, and one of the chief objects of the workshops should be the equipment of such a museum. Finally, a very important feature of the engineering school was the testing department. Here the practice of making accurate measurements, the necessity for which had been constantly pointed out in the elementary school, might attain its highest development. There were many large manufacturing towns in this country in which no testing machine existed. In such towns this department might become a small source of income to the college. In conclusion, he alluded to the very great service rendered to technical education by Sir Joseph Whitworth. When the Whitworth scholarships were first founded there existed in the science classes of the country a certain amount of machinery to enable the workman to study science. With the growth of technical education these facilities had increased and assumed a more practical aspect, and consequently the Whitworth scholarships themselves had become more valuable to the country. One generation of Whitworth scholars had become the teachers of the next, and as the facilities for technical education became greater, instead of the larger institutions of the future eclipsing those of the past, we should look back upon the gift of Sir Joseph Whitworth as that which in great measure had rendered those larger institutions possible.

## ROMAN ALTARS IN BRITAIN.

A REPORT was read by Mr. Blair at the last meeting of the Newcastle Society of Antiquaries on the Roman inscribed altars at Housesteads. It was as follows:—At the monthly meeting held in December last the writer of the paper brought under the consideration of the society three objects of Roman antiquity lately dug up at the station of Borcovicus—the first a statuary group, of which, however, a considerable portion had been detached, the main feature being a statue in the garb of a Roman legionary soldier, and two altars apparently dedicated to Mars by German soldiers serving in the Roman army in the Frisian battalion. Inasmuch as a Teutonic epithet is applied to the god, and coupled with him were two Teutonic divinities, it seemed expedient to the society to submit these objects to the consideration of the authorities of the University of Berlin. In the meantime Mr. Thompson Watkin, of Liverpool, author of "Roman Lancashire," a diligent and persevering antiquary, favoured Mr. Blair with a paper on this subject, which was read at the monthly meeting in January last. Subsequently he received an exhaustive paper from Professor Hübner, of Berlin, one of the learned men selected for the compilation of the great work, "Corpus Inscriptionum Latinarum," who is a perfect master of the English language, writes it correctly, and speaks it fluently. His paper was read at the monthly meeting in March last, and has since been revised by him and extended up to the present time. In the month of June last the resumption took place of the work of excavation at Borcovicus which was promised at our meeting in December last, when the first object discovered was the missing portion of the statuary group, being one side of it, and which was found to be less injured by time and exposure than the other side; and it is now clear that the martial figure had on each side of him a nude figure, apparently floating in air, holding in one hand a palm branch and in the other a garland or chaplet. The pencil of our colleague and secretary, Mr. Blair, has supplied us with an accurate drawing of this portion of the group, which, being engraved, has been added to the portion first discovered. The excavators next came upon a Roman well, filled to the brim, and to an extent of more than three feet above it with accumulated earth, in which was found a copious spring of pure water, affording one of many examples of the appreciation by the Romans of the numerous springs which gush from every hill and flow through every valley of Western Northumberland. The excavators then came upon two altars of hewn stone, very carefully finished, and ready to receive inscriptions. It seems to have been the practice of the priests of the pagan temples to keep in store blank altars till they met with a customer who would pay for the privilege of inscribing them. It will be remembered that in the well of the goddess Coventina there were found a dozen blank altars. On opening out the grass-grown ruins of the temple of Mars it was found that our utilitarian predecessors of the middle ages had removed for building purposes a large proportion of the building stones, leaving behind them some of the latter and a large heap of rubbish. The remaining stones have been removed and the rubbish examined without meeting with other objects. Several exploratory trenches were cut in various parts of the Chapel Hill, but no buildings could be found *in situ*, and the very foundation-stones have been taken up and removed. After four weeks of labour, the excavators took a final leave of the Chapel Hill of Borcovicus.

The Rev. Dr. Bruce said they were much obliged to Mr

Clayton for continuing these excavations and writing this paper. Men were still at work at the new series of buildings which were discovered at the Chesters two or three months ago, and which were coming out grandly.

The President said it must be a subject of unmixed satisfaction to them all that Mr. Clayton was still engaged in his antiquarian researches; in his ninety-third year he seemed to be as clear in his intellect and as acute in his researches as ever.

Mr. Thomas Hodgkin said these last discoveries at the Chesters seemed to be exciting a great amount of interest among Germans, as it was possible they might throw light on the social political condition of ancient Germany. The god to whom the altar was dedicated was called "Mars Thingsus." It was quite certain that Thing was the name of the old German popular assembly resembling our Parliament; it was called the *Folksthing*. The German popular assembly was specially under the control of the gods, and the priests had great influence to keep peace; and the impression was that "Mars Thingsus" was Mars who ruled the parliament. The two floating figures on each side were supposed to be divinities who maintained order and adjudged the prize in the popular assembly. This seemed fanciful, but it was the idea of the Germans, and this matter was exciting a great deal of interest among German scholars.

### THE DEVONSHIRE ASSOCIATION.

THE twenty-third annual meeting of the Devonshire Association for the advancement of science, literature, and art, was held last week in Newton Abbot. The following abstracts of some of the papers are taken from the *Exeter and Plymouth Gazette*:—

A report was read from the Committee on Works of Art in Devonshire, which commenced with a tribute to the memory of their genial and valued colleague, the late Rev. Treasurer Hawker, and an expression of the deep regret at the loss of one who took a warm interest in their work, and who, but for the illness which stayed his active pen, would have contributed to this year's proceedings. The committee continued their descriptive account of the works of art preserved in the public buildings and places in Exeter—a complete and detailed catalogue of the paintings and sculpture at the Bishop's Palace, the Devon and Exeter Hospital, the Workhouse and Offices of the Corporation of the Poor, the Grammar School, the Albert Memorial Museum, the Castle, the Hall of the Vicar's College, and on Northernhay and other public places in the city. By the time the monumental sculpture of the Cathedral and other city churches should have been similarly dealt with, the pages of their transactions would contain the most complete account that had been published of the public treasures of art in the Cathedral city. They hoped in another report to present a similar view of the public collections in the boroughs of the county. In this direction some progress had been made, the report containing notices of the portraits of public men in the town halls of Barnstaple, Torquay, Tiverton, and Torrington.

An interesting paper, giving "Notes on the History of Highweek," was read by the Rev. S. G. Harris, the rector of the parish. The history of this old parish, he remarked, could be traced back to the times of the Roman Invasion. It played important parts in the stirring times of the Conquest, and was then known by the name of "Teignwick." From MSS. which affected the parish, and other evidence, he had come to the conclusion that the highly-interesting Bradley House was built in the seventeenth century, and was probably the work of Richard Yard, who succeeded the family of Bussell, from whom the town of Newton Bushel derived its name. Some interesting information was given by Mr. Harris relative to Highweek Church since its dedication in 1428, adding that the mother church was at Kingsteignton. He gave a brief account of the religious provision for the district in ancient times before the building of the present parish church. The "chapel of Teynewick," i.e., the church which stood previously, where in its commanding and unrivalled situation Highweek Church now stood, was said to be mentioned in a deed of Bishop Brewer between 1224 and 1244; and again in a Bull of Pope Innocent III. in 1245. It was also mentioned in the "Taxation" of Pope Nicholas III. about the year 1288. Until the early part of the fifteenth century this ancient building enjoyed all parochial rights but that of sepulture, and this right was granted by Bishop Lacy, of Exeter, when the present church at Highweek with its burial-ground was dedicated to All Saints in 1428. It was somewhat uncertain when Highweek first became a parish, but probably between the years 1196 and 1244.

Mr. J. Brooking Rowe prepared a paper on the recent excavations made at Buckfast Abbey, which has been acquired by the monks of the Order of St. Benedict, and is being restored by them. The paper, which was read by Mr. R. N. Worth in the absence of its author, stated that the modern house at Buckfast, the ruins, the site of the abbey, and all the rights and belongings of the abbey had passed from private hands into the possession of the children of the Order above named, and that for the first time for nearly 350 years divine offices were again sung and said within

the precincts of the abbey of Our Lady of Buckfast on October 9, 1882. The monks, who were now in possession, belonged to a community founded by Father John Baptist Muard, which was expelled from France, and religious life had once more commenced in a place hallowed by the memories of more than ten centuries. At the time these monks first acquired the site they were not aware that they had become the owners of more than the modern house and the so-called Abbot's Tower. A very ugly temporary chapel was erected by them, and plans were drawn for a new church and conventual buildings. Fortunately, however, the monks were encouraged by Mr. St. George Mivart, who became interested in the matter, to undertake the work of excavation. The monks themselves carried out the task of unearthing the foundations under the direction of their companion and friend, the very intelligent and most courteous Father Hamilton, assisted by Mr. Frederick Walters, the architect of the community. The modern house was erected in 1806, and covered but a small space of the ancient site. It was built on the west side of cloister garth, and apparently but little of the monastic building was incorporated with it, the vaulted passage being the only part that could be identified. The whole of the foundations of the old abbey had been uncovered by the monks, and were found to be of a perfectly typical Cistercian foundation. The Duke of Norfolk had undertaken to restore the Abbot's Tower, and it was further proposed to re-erect on the lines of these unearthed foundations the abbey as it formerly existed, in the Perpendicular style.—Mr. Windeatt pointed out the importance of these excavations, and their results as affecting the discovery of the ruins of other abbeys. For instance, at present there was no trace existing of the old priory at Totnes, but if search were made the foundations might be found.—Lady Bowring asked whether the existence of any guest-chambers had been traced at Buckfast, as was the case at the abbey at Furness?—The Rev. Canon Brownlow said he was not aware that such chambers had been discovered. The abbey, he believed, dated as far back as the tenth century.—Mr. Worth said he believed the abbey existed previous to the tenth century, and that, with the exception of one or two houses in and near Exeter, it was the oldest religious establishment in the county.—Mr. Amery said that in many parts the turf only had to be removed to reveal the foundations of the abbey. If the site had been under tillage instead of in pasture, it was probable that the discovery would have been made long before.

### THE RESTORATION OF WESTMINSTER HALL.

A QUESTION was asked by Mr. Peddie in the House of Commons as to whether, having regard to the important effects which the proposed work on the west side of Westminster Hall would have on the architectural character of the group of buildings of which the hall forms part, and to the insufficiency of the opportunities which have been given for consideration of the designs, the First Commissioner of Works would postpone till next session submitting an estimate for the works, and would agree to the appointment of a Select Committee to consider the question of the best mode of dealing with the west side of the hall.

Mr. Shaw-Lefevre, in reply, said:—When I laid Mr. Pearson's plans before the House, about three weeks ago, I stated that if I found that there was likely to be serious opposition to them on behalf of members, I would refer the subject to a Select Committee. Since then I have been in communication with a large number of members in all parts of the House, and I find that there is a general concurrence of opinion favourable to these plans. There are some few exceptions, but that must be expected to any scheme; the general verdict, however, is certainly favourable. Under these circumstances I do not think it necessary to refer the question to a committee, and I shall ask for a vote during the present session to commence the work during the autumn. This is the more necessary as the walls of the hall were much injured during the past winter, and I am unwilling to expose them to the injury of another winter. There is, however, one part of the work which cannot be commenced at present, namely, the raising of the towers at the north end of the hall. The vote I shall ask for will not include any money for this purpose. This part of the work will stand over, and hon. members who object to it will have an opportunity of raising the question next year.

Mr. Peddie asked the right hon. gentleman whether he was aware that all the architectural journals had written strongly in disapproval of the designs, and whether he had not received from the Society for the Protection of Ancient Buildings an urgent request to postpone the matter until next year, in order that the public as well as the members of the House might have an opportunity of considering it.

Mr. Shaw-Lefevre said no doubt two architectural papers had written against the designs, but he observed that they were not unfrequently critical of such proposals. The Society mentioned had asked him to postpone the consideration of the scheme, to which it was not altogether unfavourable; and he would consult the architect with reference to some details, and would communicate to the House any changes therein.

The Rev. Prebendary Venables writes :—A great mistake was made when the law courts which masked the south wall of Westminster Hall were so hastily pulled down ; a still greater mistake will be made if Mr. Shaw-Lefevre's designs now presented to Parliament are carried out. I call the designs Mr. Shaw-Lefevre's rather than Mr. Pearson's, for though the architectural element is his, the essential features of the plan were imposed upon that eminent architect by the First Commissioner's somewhat ill-considered impetuosity in destroying buildings which might much better have been spared. Though in a different style than that now popular, they were admirable examples both of design and construction ; and, as members of Parliament have told me, they would have served a most useful purpose as additional committee rooms.

The demolition of Sir John Soane's law courts laid bare the long-unadorned flank of Westminster Hall, which, never being intended to be seen, and from the first probably hidden by the kitchen courts, and other domestic offices, of the palace, is as unattractive—I may be pardoned for saying, as ugly—as might be expected under such circumstances. The thankless task of making this long wall presentable was imposed on Mr. Pearson, and though my excellent friend has acquitted himself *à merveille*, and the two-storeyed cloister with which he proposes to conceal that which has been so unwisely revealed is in itself a beautiful composition, not even his genius can give a pleasing effect to a long, low building, standing, moreover, on a hill, surrounded by buildings of much greater elevation than itself. I repeat that the whole thing is a mistake. It will be far wiser to acknowledge that it is so than at great cost to perpetuate it and parade it before the eyes of the world.

The best thing to be done now is to cancel the existing plans, with all their excellences, and instruct Mr. Pearson to prepare designs for a building following the grand line of Kent's much-regretted Palladian front, leaving a courtyard between it and the south wall (it is a misnomer to call it the south front) of Westminster Hall, which will thus be perfectly accessible to all architectural antiquaries who may desire to examine the remains of Rufus's Norman hall, and the other relics which Mr. Pearson has so ably described in his very interesting report, but with its baldness masked from public view, as it was always intended to be.

Mr. J. J. Stevenson says :—The Government invite criticism on the plans for the restoration of Westminster Hall by their statement that no objections have been made to them. The plans are lying in the library of the House of Commons, where few can see them, where proper examination is difficult, and discussion of them is practically impossible. It would be an error to take silence for acquiescence. Of those who have seen them who may pretend to an opinion many are dissatisfied. It might be invidious for one architect to criticise another's works, but an architect's reasons for a restoration are fair subjects for argument.

Mr. Pearson has found a small piece of coping on one of the great flying buttresses, which, it may be admitted, marks the top of a building between them, and some grooves cut across these buttresses which indicate the position of a lead roof.

On this evidence Mr. Pearson builds a high two-storeyed cloister among the buttresses, shutting out them and the windows of the hall from view, asserting that this was the original design. But the coping and the grooves are of the rudest design, obviously not contemporary with the buttresses. The proof of this is that Mr. Pearson does not reproduce them in his restoration, but gives a proper parapet and roof of the period. They are too rude and occasional to be copied, and they are obviously no part of the original design, but a later addition which cuts into it anyhow. This piece of stone is far too weak and loose a peg to hang so large a building on. On his own showing, as proved by his plans, his evidence is unreliable and even false.

This might not matter if the new building were useful, though perhaps that should not be the first consideration in dealing with the most interesting relic of London. A use has to be found for it, and it is proposed to make it a carriage drive, which will be eight or nine feet below the level of the street outside. The upper storey, it is said, will be useful for keeping documents. The raising of the towers and the alteration of the north front, in order, as Mr. Pearson says, to bring it more into harmony with Barry's Westminster Palace, are questions of taste. But surely the hall should keep its own individuality and simplicity, and not copy the perhaps too exuberant ornament of the modern building.

Objections on grounds of taste and common sense might be made to the excrescence which is to jut out at the north-west corner of the hall, concealing it from approach in this direction ; but enough may have been said to show that some further discussion of the plans and some opportunity to the public of seeing them are advisable before the money is voted for them. The postponement for some months of the convenience of the semi-subterranean carriageway and the store for papers will not be a serious public loss.

The question is one of the most important of its kind. It involves the preservation of Westminster Hall, the completion of Barry's design of Westminster Palace, and additional accommodation for the House of Commons. If the original mediæval arrangement were followed, the space on this side of the hall

would be a court enclosed by buildings on the west. This was Barry's plan, and there is something to be said for it. It conceals the sunken condition of the hall, it would allow more of the ancient work to be left than would be proper if it is left open as the main front of a great building, and it would give additional accommodation, which is much needed. But, on the other hand, it would close up the open space which has been obtained between the hall and St. Margaret's Church by the removal of the law courts.

Another solution is to make the new cloister only one storey high. This would enclose the original Norman walling recently discovered, which Mr. Pearson wishes to preserve, and possibly some purpose could be discovered for it more useful than a carriage-way deep sunk below the level of the streets beside it. Other modes of treatment might, no doubt, be suggested. The question is a difficult one. There is a strong feeling among many, founded on good reasons, that the proposed solution is objectionable on many grounds. A little delay would be better than a wrong decision.

## BUILDING REGULATIONS IN SCOTLAND.

THE Bill which was introduced by the Government for the purpose of securing uniformity in public health legislation in Scotland has been withdrawn. It was so greatly altered by the Select Committee as to become a different measure. According to the *Glasgow Herald*, clauses 118-125 of the amended Bill relate to private streets. Several amendments have been made on these clauses. Clause 118 has been amended so that it is only lawful for commissioners to compel a badly-made private street "to be freed from obstructions and to be properly levelled, paved, or causewayed," &c., when and after "houses or permanent buildings" have been erected on "one-fourth of the ground fronting the same." As the clause previously stood, it was lawful for the commissioners to cause such streets to be put in similar condition when "they were formed or laid out." Clause 125 as first framed allowed private streets to be kept in order by temporary works where it was inexpedient that such streets should be causewayed or flagged, &c., to the full extent ; and it at the same time declared that such temporary works should "not be continued beyond a period of seven years." In the amended clause this period is extended to "fourteen years," and the earliest date at which such temporary works must be replaced by permanent paving is fixed at two years after the execution of the temporary works or any renewals thereof. Clause 141, which regulates the "width of streets," has been very much altered by the Committee. While the width of streets is nominally the main subject dealt with by this clause, the height of dwelling-houses and buildings is also determined by it. Before being amended, this clause dealt with "streets" only, and provided that no dwelling-house should be built on any street of a height exceeding "the width of such street." The amended clause, although no such change is intimated in the rubric, now deals with "courts," as well as "streets" ; and it increases the maximum height of dwelling-houses in "streets" and also in "courts"—by naming them together in this relation—to "one and a quarter times the width of such streets," and furnishes no clearer standard for determining the maximum height of houses in "courts." In other words, the effects of the change thus made upon the clause will be to increase the maximum height of buildings in the narrowest streets from 36 feet to 45 feet in height. This clause as originally framed further provided that in a mews or other lane of a given width—the minimum width being 12½ feet—in no case should the buildings in such lane "exceed the width of the lane" ; now the clause reads, "in no case shall the dwelling-houses fronting such lane exceed in height one and a half times the width of the lane." By this change the maximum height of buildings used as dwelling-houses in the narrowest of such lanes is raised from 12½ feet to 18¾ feet, and this limitation is now put upon dwelling-houses only. In order seemingly that the very fullest financial advantage might be derived from the amendment which thus increases the maximum height of buildings in streets, the clause has been lengthened by a new proviso determining that in cases where "a building is situated in two streets or courts of different levels the height shall be measured from the street which lies on the higher level. The Committee have apparently assumed that for all practical purposes in connection with building regulations as to height and free space "courts" and "streets" required identical treatment, and have accordingly deleted clauses 142 and 143 of the bill as remitted to them. The former of these clauses fixed the minimum clear "width of courts," and the increasing free space necessary in such as the houses became more numerous, in the buildings built round them, and it also determined for purposes of ventilation the minimum width of entrances to such courts, and fixed that these entrances should be "open from the ground upwards." The latter clause, 143, fixed the maximum height of houses in courts in relation to the width of the court "at its narrowest part." It appears far from clear that clause 141 can, as amended, in any measure carry out what these rejected clauses, 142 and 143, provided for in the way of regulating the height of buildings and the extent

of free space for light and air in "courts," as distinguished from streets. Clauses 146, 147, and 148 of the Bill dealt with the erection and removal of iron gates across courts and streets. 146 empowered Police Commissioners to erect such; and clauses 147 and 148 gave them power to cause property owners in such courts or streets to alter or remove them where they were obstructions to traffic. Where any such alteration was requested, in cases where the gates complained of had been erected by the consent of the commissioners, given either before or after the passing of the Act, the removal or alteration required was to be done at the public cost. In the amended bill the latter two clauses do not appear, and these contingencies are not now provided for. Clause 146, which alone remains, simply authorises the erection of such gates, and regulates their use. Clause 163—dealing with open space in rear of houses—has been a good deal altered by the Committee. As framed, it sought to provide against an ascertained defect in the Glasgow Police Act—the clause in which Act, regulating open spaces in back courts, has been constructed to mean, or at least sanction, the following peculiar arrangement as affecting free space for light and air in the rear of houses, viz.:—That in cases where a front and a back building, or ground sufficient to admit of the erection of two such buildings, belonged to the same owner, the free open space for both buildings might be one-half the extent of what would be required if such properties or ground had belonged to different owners. To meet this difficulty, and to secure proper free space for all buildings irrespective of the accident of ownership, the clause as first framed declared that the open space necessary for light and ventilation should "exclusively belong" to the building to which it was attached, the words "exclusively belong" have been deleted by the Committee, and the words "directly attached" have been put in their place. An important addition has also been made to this clause to the effect that in cases where buildings which have been once used for dwelling-houses and have been subsequently altered and used for business purposes, are "wholly or partly destroyed by fire," and the owner desires to re-erect them for dwelling-house purposes, it shall be competent for the owner to do so without reference to the restrictions of the clause as to open spaces; and the commissioners shall have power to enforce these restrictions only upon making compensation to the owner for the loss he may sustain in consequence of the operation of such restrictions; where the commissioners and owners fail to agree as to the amount of compensation to be paid, the amount is to be determined by the sheriff. Clauses 194-202 deal with the Dean of Guild Court. Before amendment clause 194 did not put "alteration of existing buildings" under the jurisdiction of the Dean of Guild Court; the clause as amended does so. As originally drawn this clause provided that "nothing herein contained shall be taken to restrict the jurisdiction of any Dean of Guild Court existing at the commencement of this Act," it now provides that "nothing herein contained shall be taken to restrict or augment the jurisdiction," &c. Clause 195 provides for the establishment of such courts in burghs where none existed at the commencement of the Act, and clause 196, when specifying the constitution of such court, strangely omitted to name as one of its members the Dean of Guild in burghs having a Dean of Guild. This omission is rectified in the amended clause. Clause 198 as drawn opened with the declaration that "the Town Clerk of a Royal or Parliamentary burgh shall be clerk of the Dean of Guild Court." The amended clause is shortened by omitting all allusion to the "Town Clerk." These are the main points in which differences occur in this group of clauses. Among the clauses relating to sewers few amendments have been made. In clause 226, relating to distilleries or other works, the definition of prohibitory matter originally covered what was "offensive or dangerous to health," it is now limited to what is "injurious to health." The section of the Bill dealing with drainage of houses has had a new clause added (225A) providing for the proper ventilation and trapping of all house drainage; and the clause (236) empowering the inspection of drains and cesspools by the surveyor is now amended by making it imperative that he "shall inspect any drain or cesspool or reservoir when requested by the medical officer of health or the sanitary inspector."

### ARCHÆOLOGY IN KENT.

THE members of the Kent Archæological Society held a meeting in Sevenoaks and the neighbourhood on Wednesday and Thursday in last week. Thirteen years have elapsed since the former meeting was held there. The annual report stated that during the year forty-six members had joined the society. It was expected that the volume on Church Plate in Kent might be issued in the course of next year. Descriptions of nearly two hundred sets had been received, making four hundred in all. Earl Sydney, Lord Lieutenant of the county, was elected president.

Sundridge Church, near Brasted, was first visited, and was described by the Rev. Canon W. Scott. The body of the church is Early English, but, with the exception of those in the clerestory, the windows are Perpendicular. There are Early English arcades

north and south of the nave, each of three bays, and clerestory of small quatrefoil windows. The loftiness of roof occasioned by the clerestory, and the grace of the lofty arcades, gave a character to the building. Traces of the shafts of an Early English east window might be seen at the sides of existing Perpendicular windows of five lights. The aisles were both of them raised during the fifteenth century; they and the tower were of the Perpendicular style. Traces of the earlier aisle roof beneath the clerestory window would be seen in the south aisle. The doorway of the rood loft stairs remained in the south chancel at its west end. In the north chancel, at the east end, was the altar tomb of John Isley, sheriff of Kent, who died in 1484; the conventional Tudor flower was seen upon its cresting. The brass effigies of Roger Isley, who died in 1429, and his wife were at the back of the tomb.

At Squerries Court, near Westerham, the members were received by Lieutenant-Colonel Warde. It is a seventeenth century red brick mansion, and is interesting from its connection with Wolfe. It was while in the grounds that he received his commission as major-general, with command of the expedition to North America.

The church of St. Mary, Westerham, was described by Mr. G. Leveson Gower. Few churches had, he said, a more beautiful situation, standing as it did on the edge of the hill with its three gables facing the valley below. In the grant to the Prior of Convent of Canterbury on June 18, 1290, it was spoken of as the "church of Westerham, with the chapels belonging to it." No portion of it was earlier than the thirteenth century, and no traces of any Norman work had been found during the restoration, and it was fair to infer that the first church there was the work of the Early English builders. A general scheme of alteration and enlargement took place towards the end of the fifteenth century, and the nave of the south aisle was built probably at the same time. The roof of the nave and south aisle was worthy of attention; it was a good example of the waggon roof of that date. The present reredos was erected by Lady Harriet Warde, in memory of Colonel Warde, her husband, and the tracery and painted glass of the east window were erected by his friends in memory of the late Edward Streatfeild, a grandson of a Kentish antiquary. The church has some monumental slabs, one over the south entrance being to the memory of General Wolfe, who was, however, buried in Greenwich.

Chevening, the seat of Earl Stanhope, was afterwards visited. It was built in 1630, and the design is supposed to have been after one by Inigo Jones. In the grounds are some Roman remains, which were brought over from Tarragona by General Stanhope. The church contains several interesting monuments, including the well-known recumbent figure of Lady Stanhope, who died in 1823, by Chantrey.

In the evening the members dined in Sevenoaks, under the presidency of Earl Stanhope. On the following day there were visits to Otford, Lullingstone, and Tilston.

### VENTILATION IN CONNECTION WITH WARMTH AND LIGHTING.\*

BY CAPTAIN DOUGLAS GALTON, C.B., LL.D., F.R.S.

IN this lecture I propose to endeavour to explain what are the principles which should guide us in warming our houses, and then to endeavour to show how those principles can be usefully employed in practice. We must all agree that our present arrangements are inconvenient in certain respects, so far as our towns are concerned. When we bring a large number of houses together, as we do in our great cities, the methods which we adopt for warming our houses conduce to the production of a very large amount of smoke and pollution of the atmosphere. The amount of coal which we burn is out of all proportion to the heat which we produce. Therefore, in our towns, the methods to which we resort for warming our rooms load with impurities the air which we have to breathe. Those who have been born and have lived in the heart of London, do not know what the feeling is of breathing fresh invigorating country air. The question is: how can we alter this? The first step towards alteration is to know what conditions we want to obtain. We will consider, in the first place, what advantages our present methods of warming secure for us; and next, how we can secure these in ways less hurtful to our atmosphere.

The open fire is the most favourite method of warming. So far as the production of heat is concerned, it is also the most wasteful. One pound of coal is more than sufficient, if all the heat of combustion is utilised, to raise the temperature of a room 20 feet square and 12 feet high, to 10° above the temperature of the outer air. If the room were not ventilated at all, and the walls were composed of non-conducting materials, the consumption of fuel to maintain this temperature would be very small; but we must

\* A paper read at a Conference at the International Health Exhibition.

change the air of the room if we are to live in it, or else the act of breathing would render the air so impure that we should die. The air which passes out of the room to make way for fresh air is warm, and carries some heat with it; the fresh air which comes in, if cold, absorbs heat, which brings up its temperature to that of the room. All this entails a development of additional heat. For instance, if the volume of air contained in the room above mentioned were changed every hour, one pound of coal additional would be required per hour to heat the inflowing air, so that to maintain the temperature at  $10^{\circ}$  above that of the outer air during twelve hours would require 12lb. of coal. Besides this, there is a continual escape of heat going on through the walls, windows, ceiling, &c., and thus the mere circumstances of occupation of a room entail a greater consumption of fuel than the mere 1lb. of coal in order to maintain the temperature. But the open fire consumes much more than would be necessary to keep up the heat. The principle of the ordinary open fireplace is that the coal shall be placed in a grate, to which air is admitted from the bottom and sides to aid in the combustion of the coal; and an ordinary fireplace, for a room of 20 feet square and 12 feet high, will contain from about 15lb. to 20lb. at a time, and, if the fire be kept up for twelve hours, probably the consumption will be about 100lb., or the consumption may be assumed at about 8lb. of coal an hour. But the consumption of fuel enables the open fire to perform other functions besides those of warming. It is a great engine of ventilation. One pound of coal may be assumed to require, for its perfect combustion, 160 cubic feet of atmospheric air; 8lb. would require 1,280 cubic feet; but at a very low computation of the velocity of the gases in an ordinary chimney-flue the air would pass up the chimney at a rate of from 4 feet to 6 feet per second, or from 14,000 to 20,000 cubic feet per hour; with the chimneys in ordinary use, a velocity of from 10 feet to 15 feet per second often prevails, giving an outflow of air of from 35,000 to 40,000 cubic feet per hour.

We have, therefore, to consider the open fire in two aspects:—  
1. As a method of warming; 2. As an engine of ventilation. In its aspect of warming, the radiant heat from the fire does not warm the air of the room; the rays from the fire warm the sides and back and parts adjacent to the grate, they warm the walls, floor, ceiling, and the furniture of the room, and these impart heat to the air. The form and material of the fireplace can thus assist materially the warming of the air. The rays should impinge more freely on the walls and floor than on the ceiling. A projecting chimney-piece, with a surface favourable to the absorption and emission of heat, would be more favourable to the warming and circulation of the air than one which would allow the rays to pass to the ceiling. In an ordinary fireplace the sides should be splayed, as in the Rumford form of grate; the sides and back should be of non-conducting material, with a surface favourable to the rapid absorption and emission of heat. Thus brick or tiles are better than iron for this purpose. Similarly, the degree to which the materials of the walls or floor of the room are unfavourable to conduction, but favourable to the absorption and emission of heat, will have a bearing on the capacity of the room for warmth. The open fire, moreover, has this advantage—that a person can obtain just as much or as little heat as he desires by placing himself in front of the fire or at the side. There is, however, this inconvenience about the open fire. The large volume of air drawn out of a room by the chimney must be supplied from somewhere, and consequently the very means adopted to heat the room tends to produce draughts, because the stronger the direct radiation, or rather the brighter the flame, in open fireplaces, the stronger must be the draught of the fire and the abstraction of heat.

Let us next consider what are the conditions which we require for comfort. The normal temperature of the human body is  $98^{\circ}$  deg. Fahr. If it rises much above or falls much below that, death will ensue. But the human body is a furnace in which the process of combustion is continually going on. Therefore, in order to preserve the normal temperature, the body must continually give off a certain amount of heat. By the laws of radiation, a heated body parts with its heat more or less rapidly in proportion to the low or high temperature of bodies near it. Thus, if a hot body be placed near a cold body, the hot body will radiate heat rapidly. If the hot body be near a body less hot than itself, but still hot, it will part with its temperature slowly. Let us apply this to a room. If you are sitting in a room near a cold brick wall, you feel what you think is a draught. It is not necessarily a draught at all. But the side of your warm body turned next the wall parts with its heat rapidly, and you experience a local chill. If you hang a piece of carpet against the wall, the draught is no longer felt because the carpet checks the rapidity of the radiation. Now, the chief source of heat in the open fire is its radiant heat, and as it warms the walls of the room and the furniture, it takes off any sensation of chill from the walls, &c., although the air may be comparatively cool. You must next bear in mind that the proportion of radiant heat to the total heat given out by a heated body depends on the temperature of the body. Thus, with a red-hot piece of iron, or a flame, the great part of the heat given out is radiant heat; whereas, with a body heated to from  $150^{\circ}$  deg. to  $200^{\circ}$  deg., like a hot-water pipe, a comparatively small proportion is radiant heat. Therefore, when you heat a room

by means of hot-water pipes, or by means of warmed air, the walls do not get warmed in the same proportion, and although the air may feel warm, the walls may remain cold, so that the heat of the body may be radiated to the walls and give the sensation of chill.

I confess that personally I think there is nothing to be compared with what my friend, Sir F. Bramwell, calls the pleasant, pokeable fire. But I do feel most strongly that, however much private feelings may incline us all to use the open fire, it is our duty, now that our towns are becoming so vast, to adopt some method of heating which will produce less smoke. It is not as if there was any probable and early limit to the size of London or of other large towns. They grow continuously, and London has progressed at the same steady rate since the beginning of this century. In 1851 it contained a little over 2,000,000 inhabitants, and was looked upon as vast and abnormal. It now contains 4,000,000, and is steadily increasing. The smoke destroys our light, it injures our air, it ruins our furniture, our pictures, our decorations, and with the increase of London, this must go on in an accelerating ratio. But it requires education in the people to get rid of it. The Smoke Abatement Society, under the chairmanship of Mr. Ernest Hart, sounded the first note against this gigantic evil. In response to the demand then made, many new forms of fireplace were proposed; but the practical conclusion to be derived from that exhibition was that so long as we burn our fuel in the raw state in our rooms and in our kitchens, we cannot get rid of smoke. The main object of the present exhibition is to educate the people in the science of health. The public has long felt the want of pure water, and has obtained a supply of comparatively pure water in the metropolis. The public has not yet become fully alive to the necessity of pure air. It is our business at this exhibition to endeavour to awaken the public mind to this want. So far as purity of air depends on removal of refuse from our midst, there is hope that in that respect this object may be attained, although no doubt even this simple question is much neglected. Dust is generally removed in open baskets, and emptied into open carts, in a manner which seems to have been designed for the purpose of scattering it as much as possible into the surrounding atmosphere. But the purity of air which depends upon the absence of smoke is another matter, and I fear that it will be many years before the selfishness of the community will give way on this point.

The first point to consider is, if we dispense with the use of the open fire, how can we obtain that comfort which the open fireplace gives. The comfort of the open fire is due to the warmth it imparts to the floor, the walls, and the furniture. The air of the room is warmed, not by the rays from the fire, but by the warmth imparted by those rays to those various objects. Therefore the air of the room is somewhat cooler than the walls. Now there is undoubtedly greater exhilaration produced by breathing cool air than by breathing warm air. This is readily accounted for. One cubic foot of cold air at  $32^{\circ}$  deg. Fahrenheit contains more oxygen than one cubic foot of expanded warmer air at  $32^{\circ}$  deg. Fahrenheit does. It is thus desirable that air admitted to a room should not exceed from  $55^{\circ}$  deg. to  $60^{\circ}$  deg. temperature, for comfort in breathing. This will at once explain to you why the employment of warmed air alone to warm your houses does not give comfort. If the warmed air is admitted at a comfortable temperature for breathing, viz., about  $55^{\circ}$  deg., the walls, which derive their heat from the air, will be somewhat below that temperature. The discomfort is caused by the warm body radiating its heat too rapidly to the colder walls. Therefore, if you are to abandon the open fire, but retain its comfort, you must warm the walls and floors, &c., of your rooms. If you can maintain your walls, floors, and ceilings, at a temperature of from  $55^{\circ}$  deg. to  $65^{\circ}$  deg. combined with an adequate change of air, you will not experience much inconvenience from the loss of the open fire, however much you may regret its companionship and its pokeableness.

There are four ways in which we may effect this. In three of these ways one fire in each house in a central position would be used. In the fourth the heat would be applied in the room itself by means of gas. It is probable, however, that a combined arrangement would be desirable. In all the cases where the heat is furnished from one fire, this fire would be in a close furnace for warming each house, or self-contained block of buildings; and thus the fire could be so arranged by means of self-feeding apparatus to be practically smokeless. The heat from the fire would be conveyed to the various parts of the building by hot air, hot water, or steam. Where warmed air is used, it would be necessary to adapt the house in its original construction to the purpose, because the air would have to flow up, through spaces in the walls, from the basement. Moreover, it would not be economical to bring up the air in the outside walls, because then nearly half the heat would pass direct to the outer air. The warmed air passing up the central walls of the house would part with some of its heat to the walls, and would thus enter the room at a lower temperature than that of the walls. In order to draw up the warm air into the rooms, it would be necessary to have some means of extracting the air from the room, so as to draw in the warmed air. It would not always flow in of itself in this country. Thus you see that the warming by means of fresh air involves ventilation, and moreover requires, if it is to be thoroughly efficient, that your architect

should have thought out the whole problem when he first plans the house, and before you build it; otherwise you are met with difficulties at every turn. In the method of heating by hot air alone you have this further consideration. The air in the heating chamber is necessarily at a given temperature, and your house is thus heated uniformly; but it may happen, in this climate especially, that you may want one room to be warm whilst another is cool. It is generally on this account that other methods of heating have been preferred. It is to these methods of heating that I would now direct your attention. These methods are hot-water pipes, or steam pipes, led from the fire, which is placed in some central position, and arranged to accumulate the heat in those rooms or other places which it is desired to heat.

I will at once say that the arrangements hitherto made of warming by either hot-water pipes or steam pipes have not fulfilled the conditions I have mentioned as being necessary to supply the comfort of the open fire. The method adopted is to accumulate a certain amount of heating surface in a coil or nest of pipes, or in what is termed a radiator in the United States; but the plan of distributing the heat by means of a large flat surface placed close to the wall has been generally adopted. I do not wish to imply that it has not been thought of, because some few years ago, in an exhibition of sanitary appliances held at the Society of Arts, Mr. Pritchett, of Bishop's Stortford, suggested something of the sort. The apparatus consists of a series of receptacles, or cases, for water. The cases themselves were formed of ordinary plates of corrugated metal, strongly put together, but having a small interval between them so as to unroll the water, as it were, into a film, and form a succession of reservoirs of water, about 30 inches in height, more or less, as is required, but only from  $\frac{1}{2}$  inch to 1 inch in thickness, enabling them, therefore, to be placed continuously as a dado, or as a series of panels, round any room or building intended to be warmed, and occupying scarcely any appreciable portion of the space of the room or building. The corrugated form given to these reservoirs not only increases the area of the external surfaces, back and front, and imparts strength to the vessels, but secures a certain amount of friction in the action of the warmed water within the vessels, which predisposes it to part with its heat during its circulation. I have never seen this applied in practice on a large scale. These panels might conveniently form the dado of a room, and if of 6 feet high, would insure the comfort of the occupants of the room, as they would effectually prevent persons in the room from radiating the heat from their persons to the surrounding walls. Such panels all round the room would especially lend themselves to warming fresh air to be admitted into the room. Mr. Pritchett proposed that these should be warmed by the circulation of hot water; but it is certain that it would be more advantageous to employ steam to heat them if they were established on a large scale. In England steam is not much employed for heating. We are prejudiced against it. We fear accidents. It is, however, a method of conveying heat which is eminently suited to use on a large scale; and if we are to hope to abolish our smoke nuisance, it is by methods of heating on a large scale only that we may succeed. Steam heating is extremely simple in its application. Steam is easily led to great distances. Steam-heated pipes are hotter than hot-water pipes, therefore their effect in warming the air in contact with them is also greater; and, therefore, when heating is required on a large scale, it will be found that it is more economical to use steam pipes than hot-water pipes; besides which, the pipes may be smaller, and thus in both ways expense is saved. Highly heated steam-pipes, moreover, radiate a large portion of their heat to the walls and furniture of a room.

Heating by steam is universal in the United States, and the usual system may be described as follows:—The steam is conveyed from the basement along pipes to the room or passage where it is wanted to be used, and there it is passed into a cluster or coil of pipes called a radiator, which gives an enlarged heating surface. The cause producing the circulation throughout the pipes of the warming apparatus is solely the difference of pressure which results from the more or less rapid condensation of the steam in contact with the radiating surfaces; a partial vacuum of greater or less amount is thereby formed within the radiating portions of the apparatus: and the column of steam, or of water, equivalent to this diminution of pressure, constitutes the effective head producing the flow of steam from the boiler; while the return current of condensed water is determined by the downward inclination of the pipes for the return course. Therefore, the flow-pipe should be carried in as direct a line as possible from the boiler to the highest point; all the coils for heating should be placed on the return pipe, which should be laid in a uniformly descending line back to the boiler, so arranged as to prevent the lodgment of any condensed water on its way there; because if condensed water lodges in the pipes most unpleasant and startling noises result. It is a source of economy in steam heating that the condensed water should flow back to the boiler. This is what is called closed circulation, with separate supply and return mains, both of which extend to the furthest distance to which the heat has to be distributed. It is, however, possible to carry the steam and bring back the condensed water by means of a single main, which answers at once for both the supply and the return, either with or without a longitudinal parti-

tion inside it for separating the outward current of steam supply from the return current of condensed water. If more convenient, the return of the condensed water to the boilers may be dispensed with, and the steam may be applied in what is called the system of open circulation, where a supply main conveys the steam to the radiating surfaces, whence a return main conducts the condensed water either into an open tank for feeding the boiler, or into a drain to run to waste, or for use as hot water, the boiler being then fed from some other source; in either case suitable traps have to be provided on the return main, for preserving the steam pressure within the supply main and radiators.

The difficulty of steam heating lies in regulating the temperature of the pipes. With hot water you can have your pipes heated to anything you like from 50° to 180°; but with steam pipes it is different. The heat is got up very rapidly when the steam is turned on, and goes off very rapidly when turned off. There are various arrangements for regulating steam heating when applied to warm inflowing air. In the New York Hospital the incoming air is warmed by coils of steam pipes, and generally to a considerable temperature; but in order to prevent the warmed air entering the wards at too high a temperature, this hot air is passed into a mixing chamber, to which cold air can be admitted at will, so that the hot air can be mixed with cold air to the extent necessary to moderate its temperature before it is allowed to flow into the wards. There is, however, one great advantage possessed by coils of steam-heated pipes: they give out a larger proportion of radiant heat to the walls than is given by hot-water pipes. You can easily understand how much simpler it would be to warm Mr. Pritchett's dados and wall panelling by steam pipes carried through them instead of by hot water.

The next way in which heat can be applied is by means of gas. A gas jet warms any surface in contact with it. If, therefore, you enclose a gas jet in a metal case, and if you bring air to feed the gas burner from the outer air, and carry away the products of combustion also to the outer air, you can use the heat of the metal case to warm the surrounding air in the room, whilst the fumes of combustion from the gas will be taken outside and do no harm to the air of the room. Gas jets might thus be applied with the greatest ease to warm Mr. Pritchett's dados and wall panels, the gas jets being placed inside the dado, and the products of combustion carried to the outer air. Mr. Boyle has invented a very efficient method of applying gas to warm inflowing air at an ordinary ventilator. It is in use at the Guildhall. The fresh air inlet has placed in it a pipe which is coiled round. A gas burner is placed at the bottom of the pipe, separate from the air of the room; the products of combustion pass up the coiled pipe and then down and out to the open air, the pipe being warmed by the heat they give out in their passage, and the fresh inflowing air being warmed by the pipe. Of course, in all these arrangements air must be extracted by flues or fans or some other method, so as to insure a due circulation of air. But however advantageous gas may be in the methods of its application to warming, and I do not hesitate to say that it can be easily applied so as to be hygienically perfect in that respect; moreover, you can apply your heat at the exact point at which you want it. You can so arrange it as to give out a low degree of heat for warming fresh inflowing air, or to give out heat to warm your dados and prevent your own body losing its natural heat too rapidly by radiation; or you can use it to give out a high degree of heat, and thus to furnish radiant heat to warm you by direct radiation. It has only to be carefully adjusted to produce all these advantages, yet there is this enormous drawback to its use. At the price of 3s. 6d. a 1,000 cubic feet, it would cost to effect these things about four times the price of coal. I believe that if it could be supplied so as not to exceed double the price of coal, it might be economical to use it, because you can use it when and where you desire it. You can turn it off when you leave your room, and turn it on again when you return, and in this climate, where our changes of temperature in winter are so rapid, a uniform heat applied everywhere often becomes oppressive.

Let us consider for a few minutes what is the meaning of revolutionising the methods of warming our houses in the way I now propose. We should not load our atmosphere with soot. Each of the fires in a house requires its separate chimney; and as if the householder were determined to do all in his power to make the atmosphere impure, smoke which is arrested in the chimney flue in the form of soot is periodically pushed up out at the top of the chimney into the air, not only to the detriment of the occupier of the house, but to that of the neighbours—an arrangement which may be witnessed any morning in houses where chimneys are being swept. These inconveniences result from having separate fires in every house, and for each separate object. Let us consider for a moment the amount of labour and expense entailed by the mere supply of fuel upon this separate system. Take, as an example, one house of moderate size. The consumption of coal at a low calculation will be twenty-four tons a year, which would require twelve carts to convey it to the houses; or a street such as Eaton Place would require 12,000 carts to supply it with coal. These carts entail the presence of between 2,000 and 3,000 horses, and each horse causes, by the manure it deposits in the street, an additional pollution of our atmosphere. When the coal is placed in the house,

these twenty-four tons require to be carried up in coal scuttles, each holding probably a quarter of a hundredweight. That is to say, that there would be to be carried from the cellar to various parts of the house nearly 2,000 coal-scuttles full of coal. The residue would have to be carried down again in the shape of ashes, probably to the extent of 400 coal-scuttles, independently of the proportion of ashes which get scattered from the fireplace about the room, and have to be cleaned up by the housemaid. In addition to this, the dirt engendered by the smoke and soot sent up into the atmosphere renders much additional cleaning necessary, and entails on the inhabitants of London a vast expenditure on soap, and on repainting and redecorating our rooms. Indeed, the late Miss Garrett, who was celebrated for her skill and taste as a decorator of houses, told me she had no sympathy with the movement for the abatement of smoke, because she looked upon smoke and fog as specially sent by Providence for the benefit of decorators. The labour thus entailed is wasted force. It entails vast unnecessary labour and waste of fuel. Probably, if the price of coal had remained high, as in 1875-6, we should ere now have begun to warm our houses in a more rational way. But it is not on the ground of economy that I advocate a change. It is on the ground of purity of air. So long as we pollute the air with soot, not only is the outside air impure, but the air is so loaded with dirt that the careful householder excludes it from his rooms where possible. You would all be ashamed to supply your guests at a party with bad water. If you were equally ashamed, which you ought to be, to supply them with bad air, we should soon take measures to build our houses so as to keep up a continual flow of fresh air throughout our rooms. And then we should be rapidly compelled to take measures also for warming our houses in a way which would not pollute our atmosphere.

## LEGAL.

Warwickshire Assizes.—Aug. 1.

(Before Mr. JUSTICE SMITH.)

W. WYKES v. G. H. MACDERMOTT.

ARCHITECT'S FEES.

This was an action by Mr. Wykes, architect, Birmingham, against Mr. Macdermott, a music-hall singer, for the recovery of 529*l.* for preparing plans, taking out quantities, and superintending work in connection with the erection of a theatre in Birmingham. The defendant wished to erect a theatre in which intoxicating drinks should not be sold, and which alternately was to be used for dramatic and music-hall entertainments. With the co-operation of Mr. Bennett, a builder, a site was selected in Corporation Street. An architect was required, and the plaintiff was engaged, being introduced by Mr. Bennett. Mr. Wykes considered the matter, and made some sketches. After going to look at the site Mr. Macdermott and Mr. Bennett instructed the plaintiff to prepare a plan. Defendant thought that the plaintiffs should look at one or two buildings, and he went there with defendant and Mr. Bennett. Two days were spent in this way. Drawings were afterwards prepared, which were submitted to Mr. Macdermott. On June 9 there was an interview in London with the defendant, and on June 28 defendant wrote to the plaintiff stating that every effort must be made to push forward the theatre, as they must open by Christmas, adding, "I have written to Mr. Deakin, to know how we shall send the first 500*l.*, so that there need be no delay." On July 4 Mr. Macdermott wrote to Mr. Bennett, asking him how matters were getting on, as they must open on Boxing Night, or it would have to be postponed until the autumn of the following year. In that letter he also enjoined upon Mr. Bennett the desirability of not forgetting to apply for the licence, and to make them understand that this was to be a temperance theatre for the people, and that the undertaking could not be limited. Ultimately Mr. Bennett was obliged to stop the work for want of funds, and his creditors supposing there must be something wrong, he was obliged to file his petition on September 28. Subsequently another theatre was built by another person under different circumstances. The negotiations between plaintiff, Mr. Bennett, and Mr. Macdermott came to an end, and the present action was brought.—Mr. Wm. Wykes was then examined, and confirmed his counsel's statement. In cross-examination, plaintiff said that the matter was first mentioned to him by Mr. Bennett on March 23. He would swear that before March 1 he was not in correspondence with Mr. Bennett. Defendant told him he had got a splendid idea, and took witness to look at the land. His first instructions in the matter were undoubtedly received from Mr. Macdermott. He learned afterwards that Mr. Bennett was interested. Mr. Bennett failed for a considerable sum—nearly 25,000*l.* He believed Mr. Bennett had 450*l.* worth of materials on the place when he failed. He did not send in his account for the money he was now suing for.—Mr. Sharp spoke to being present when the conversation took place, and to the defendant saying he should like some one to join him in the project, and Mr. Bennett

said he would do so. He also spoke to being present when the plans were discussed in the first instance, and on that occasion both Mr. Bennett and Mr. Macdermott suggested alterations.—Mr. W. T. Bennett, builder, Birmingham, gave evidence as to joining the defendant in the project. It was at witness's suggestion that the plaintiff was engaged in the work. Witness expended altogether between 700*l.* and 800*l.* In consequence of the matter coming to a standstill he was obliged to file his petition. In cross-examination witness said that Mr. Wykes knew he was interested in the matter from the beginning. When he failed his liabilities were 22,000*l.* and his assets 20,000*l.* Mr. Wykes was a debtor to the estate to the amount of 500*l.*

The defendant in his evidence said that from his great experience in the country he conceived the idea that a temperance theatre would be highly acceptable to the middle classes of Birmingham. He denied that he ever gave any instruction to the plaintiff to do the work. The matter was simply talked of in a friendly way. Witness did not say he should like to have a plan to see what could be done. He never gave plaintiff instructions to get out plans of the land in Corporation Street. In cross-examination he absolutely denied having anything to do with the scheme. Whatever he did was contingent upon his being made a partner in the concern, and he was not to pay the 500*l.* until the partnership deed was drawn up.—Mr. Deakin, Mr. Bennett's solicitor, also gave evidence.—His Lordship summed up in favour of the plaintiff, and the jury almost immediately returned a verdict for the plaintiff.—His Lordship directed that the reasonableness of the charges should be referred to a competent surveyor.

## ART WORKMANSHIP.

**Augustinian Memorial.**—A Saxon cross, reproduced from one at Sandbach, is to be erected at Cottington, near Ebbs Fleet, in the Isle of Thanet, which is said to be placed where St. Augustine landed on his mission to England. The cost will be defrayed by Earl Granville, Lord Warden of the Cinque Ports. The west front exhibits the Christian legend. On the encircled cross at the head of the shaft are the four emblems of the Evangelists. On the panelled shaft below are represented the Annunciation, the Virgin and Child, the Crucifixion, and the Transfiguration, with demi-figures of saints and angels. On the north side the theme is continued by figures of the twelve apostles, each bearing his appropriate emblem, Judas being shown with a beast's head, as was the common practice in early symbolism. On the south side are a series of fourteen figures of early Christian martyrs, commencing with St. Stephen, and following with SS. Bartholomew, Agnes, Sebastian, Margaret, George of Cappadocia, &c., also with characteristic emblems. The east front of the circular cross is filled in with Runic ornament, which continues nearly half-way down the shaft, when the design breaks into diamond-shaped panels, filled with figures in the following order:—"St. Alban, the proto-martyr of England" (A.D. 303), "St. Augustine, attended by Monks," and "Ethelbert, King of Kent." The shaft, a monolith about twelve feet high, has a bold cabled beading on its four angles, and between that and the panels, on the two wider faces, is an elegant pattern of the string ornamentation so often met with in Runic carving. Including the base and cross, the monument rises to a height of about twenty feet. With the possible exception of some of the figures, it is a strict imitation of the original at Sandbach. The stone is from the Doulting quarries. The cross is the work of Mr. Roddes, of Birmingham.

## ARCHÆOLOGY.

**Britanno-Roman Inscriptions Discovered in 1883.**—Mr. W. Thompson Watkin has published a report on the inscriptions discovered in Britain during the past year. The discoveries include an altar of some interest found at Hale, in West Cumberland, two milestones at Llanfairfechan, and an altar with a most curious and puzzling inscription at the great camp of Borcovicus (Housesteads) on the Wall. The inscription, as read and expanded by Mr. Watkin, runs:—"Deo Marti Thincso et duabus Alasiagis Bedæ et Funmiterræ et Numini Augusti Germani cives Tuihanti votum solverunt libentes meritis." This, or rather the companion and almost identical inscription on another altar found at the same place, has already been discussed by Mommsen in the latest number of *Hermes*, and Mr. Watkin himself has contributed an essay on the subject to the *Bulletin Epigraphique de la Gaule*. Mr. Watkin takes "the two Alasiagæ" to be "local goddesses of continental *pagi*," called, after places in those *pagi*, Beda and Fimmilena. He further suggests that in the name of these deities we have the germ of the name for Alsace. He omits, however, to notice the fact that the old High German "alah"—"holy"—occurs in other similar words. Thus we have "Matres Alatervæ," "Matronæ Alagabiæ" (elsewhere simply "Gabiæ" without the prefix) on inscriptions found in the Rhine district.

### CHURCH BUILDING AND RESTORATION.

**Jamesley.**—St. Andrew's Church has been reopened after undergoing renovation. The whole of the work has been designed and superintended by Mr. Robt. J. Johnson, architect, of Newcastle-upon-Tyne, and executed by Mr. Ralph Sanderson, builder, of that city.

**Northfleet.**—The memorial-stones of a new mission chapel, at Lower Northfleet, have been laid. The chapel is being erected by Mr. Tuffee, builder, of Gravesend, from the plans of Mr. Bell, architect, of London.

**Chatham.**—The memorial-stones of a new chapel have been laid. The building is calculated to accommodate about 300 persons, and there will be school accommodation for 250 children attached to it. Mr. C. E. Skinner, of Chatham, is the builder, and the plans are by Mr. J. Kingwell Cole, of London.

### NEW BUILDINGS.

**Workington.**—For several months the Workington petty sessional business has been conducted in a building in Washington Street, owing to very extensive alterations and enlargements which have been going on at the police station and courthouse in Nook Street. Ten new cells have been made in the station, and the courthouse has been very much enlarged and thoroughly renovated. It is now large and airy, and has been arranged with a view to securing the greatest comfort and convenience to all who have business to transact at the place. The bench is well elevated, and has ample space for the passing to and fro of the magistrates. Leading off one end of it is a commodious retiring-room, with a private entrance from Pinfold Street. The magistrates' clerk's table and table for the superintendent and inspector of police are immediately below the bench. In front of this is the solicitors' table, with the witness-box on one side and the prisoner's dock on the other. Immediately behind the solicitors' table and facing the bench is the reporters' table, which is sufficient for the accommodation of seven or eight reporters. The woodwork is all of carved and panelled oak, and has a light, cheerful appearance. The work has been carried out under the supervision of Mr. R. S. Marsh, surveyor to the Cockermouth Local Board, from plans and specifications by Mr. Cory, Carlisle, the county surveyor. The building is now one of the best court-houses in West Cumberland. It has been completed within the last few days, and was formally opened.

**Bolton-le-Moors.**—In the year 1870 the sum of 30,000*l.* was left by the late Mr. Stephen Blair, of Bolton-le-Moors, to build and endow a convalescent hospital near that town, under the condition that if a site was not given or provided within a fixed time the gift would lapse, Mr. Blair not being legally able to leave money for the purchase of land, and the money would go to the family of the testator's brother, Mr. Harrison Blair. The trustees are Mrs. Harrison Blair, the Rev. Canon Powell, Mr. C. Wolfenden, Mr. Thomas Glaister, Mr. W. Hargreaves, and Mr. J. Hick. Mainly through the exertions of those who would have benefited had the site not been given, a suitable plot of five acres was found just in time to prevent the legacy to the hospital from becoming void. Mr. Knowles most generously gave the site, a plot pleasantly situated to the north of Bolton, and about half-way between Mr. Greg's house and the Bromley Cross Station. The land slopes towards the south and west, and the country around about is attractive. Since the year 1870 the money has been well invested, and has greatly increased in amount, so that a larger and more complete hospital, duly endowed, can be erected. The trustees have engaged the services of Messrs. Medland and Henry Taylor as architects. The building as now designed is divided into three departments for men, women, and children, with a central administrative block. The preliminary works of levelling, foundations and boundary walling have been already let to Messrs. Thornton & Sons, of Liverpool, and are to be pushed on with all desirable speed.

### SCHOOL BUILDINGS.

**Beswick.**—The memorial-stone of a new school for the Manchester School Board for the district of Beswick has been laid. The building will be two storeys high, and will contain accommodation for 1,100 scholars. The basement will be used as a playground. Four large schoolrooms will be provided, and twelve commodious class-rooms, and premises will also be made for a caretaker. The building is to be in brick with stone dressings. The school is being erected by Mr. J. L. Ward from plans by Messrs. Potts, Pickup & Dixon. The total cost, including the site and furnishing, is estimated to be about 11,000*l.*

**Sheffield.**—The foundation-stone of the Montgomery Hall and Sunday School Institute has been laid. The site of the proposed building is in New Surrey Street, and its situation is, all that could be desired, being easily accessible from all parts of

the town, and within comparatively easy reach of both railway stations. The building will be in the Domestic Gothic style, of worked ashlar stone throughout. The large hall will provide accommodation for 1,000 persons, and will have five wide staircases as outlets, the doors all being made to open outwards. The contract for the building has been let to Messrs. George Longden & Son, of Neepsend, at 7,696*l.*; Mr. C. J. Innocent is the architect, and Mr. Dickinson is clerk of works.

**Sheffield.**—The School Board have adopted plans by Mr. C. J. Innocent, of Sheffield, for the proposed schools at Sharrow Lane. The plans provide for the accommodation of 400 boys and 400 girls in one block, and for 300 infants in a separate building; but it is only intended at present to carry out the building of the boys and girls' departments, and the plans are so arranged that the main building can be temporarily adapted for boys, girls, and infants. The buildings are to be of stone.

**Ellesmere.**—The new college of St. Oswald has been dedicated. The college stands a little to the right of the Ellesmere and Lee road, and is hidden from the view of wayfarers by a low range of hills, which may be expected to do good service in the time to come by warding off the keen east winds. On a very clear day a view of Snowdon may be obtained. The design of the buildings is a mixture of the Perpendicular and the Elizabethan styles of architecture. The impression which strikes the visitor is that neatness and durability have been aimed at by the constructors rather than useless and costly ornamentation. The principal entrance at present is on the eastern side, but eventually the main approach will be formed on the western side. To commence with provision is only made for 200 boys. It is intended to limit the number to 100 next term, but as time goes on the original design will be carried out, and there will be provision made for 500 students. On entering by what has been termed the Founder's Gate, the visitor finds himself in a corridor 220 feet long and 8 feet in width, the masters' rooms opening on the west side. The first and second floor rooms are devoted to boys' dormitories. Passing through a spacious, lofty, and well-lighted ante-hall we come by a small flight of steps to a room which for the present will have to do duty as dining and school-room. This is undoubtedly the handsomest room in the whole building. It is 120 feet in length, 36 feet wide and 22 feet in height, measuring from the wall plate, but to the apex of the roof the height is 35 feet. The dormer windows are filled with stained glass, by which a subdued and pleasant effect is produced. Underneath the dining-hall is the gymnasium, but for a few years at least it will serve as chapel. Ruabon red bricks with Cefn stone dressings are the materials of which the building is composed, the timber throughout being the best Russian deal. The architects are Messrs. Carpenter & Ingelow, of 4 Carlton Chambers, Regent Street, London, and the works have been carried out under the direction of the committee by Mr. Garland. So far upwards of 27,000*l.* has been spent, exclusive of the cost of furnishing.

### GENERAL.

**The Dome of St. Peter's, Rome,** has been recovered with lead. The work has occupied twelve years, and has cost over 200,000 lire (8,000*l.*). The original covering was applied to the dome in an imperfect fashion, which made continuous repairs a necessity; and at last it was determined to strip off the whole envelope and substitute a new one on a better system. New lead was imported from Spain and mixed with the old lead, in the proportion of one part old to two parts new. The total weight of the new cover is given at 354,305 kilograms; and if it were spread out flat it would occupy an area of 6,152 square metres, or about an acre and a half. In stripping off the old plates, three of them were found to be of gilded copper.

**The Removal of the Wellington Statue** from Hyde Park Corner began at one o'clock on Thursday morning. It was found that the horse was too heavy to be carried over the bridges on the road to Aldershot, and the body has been cut in half.

**The Meeting of the Royal Archæological Institute** began at Newcastle-on-Tyne on Tuesday, when an address was delivered by the Duke of Northumberland in praise of the district as a field for study.

**The Ancient Church of St. Oswald, Filey,** is to be restored. Promises of subscriptions have been received to the amount of over 2,000*l.*, the estimated cost of the whole work being about 4,000*l.*

**Chiswick Parish Church** was consecrated on Saturday last. The tower of the old church has been retained, but the remainder is new. Mr. Pearson, R.A. was the architect, and the cost has been defrayed by one of the local brewers.

**A Contract** amounting to 4,700*l.* has been taken for the rebuilding of St. John Baptist's Church, at Pilling, near Fleetwood, which is to be carried out under the direction of Messrs. Paley & Austin, architects, Lancaster.

**The Glasgow Masons** have been on strike for a great part of the week. The point in dispute is an advance of a penny an hour which is claimed by the men—the present wage being sevenpence. Twenty-nine firms have agreed to the demand.

# SUPPLEMENT

TO THE

# ARCHITECT

## CONTRACTS, COMPETITIONS, AND TENDERS.

LONDON, AUGUST 9, 1884.

### COMPETITIONS OPEN.

**NORTH SHIELDS.**—Aug. 18.—Plans are required for Alterations and Additions to the Workhouse. Mr. Christopher Scott, Guardians' Hall, North Shields.

**STOCKPORT.**—Sept. 15.—Designs are invited for Public Baths. Premiums of £50, £30, and £20. Mr. Walter Hyde, Town Clerk, Stockport.

### CONTRACTS OPEN.

**ABERDEEN.**—Aug. 11.—For Additions to Midmar Parish Church. Messrs. Matthews & Mackenzie, Architects, 255 Union Street, Aberdeen.

**ALNE.**—Aug. 9.—For Building Dwelling House. Mr. H. M. Cross, 17 Blake Street, York.

**BARDSLEY.**—For Building Organ Chamber and Chancel Extension to Church. Messrs. John Eaton & Sons, Architects, Ashton-under-Lyne.

**BELFAST.**—Aug. 13.—For Erection of School Buildings, McClure Street. Messrs. Young & Mackenzie, Architects, Donegall Square East, Belfast.

**BELFAST.**—Aug. 14.—For Building School in Connection with Westbourne Presbyterian Church. Messrs. Young & Mackenzie, Architects, Donegall Square East, Belfast.

**BIRMINGHAM.**—Aug. 23.—For Erection of Kitchen and other Buildings at the Workhouse. Mr. W. H. Ward, Architect, Paradise Street, Birmingham.

**BROMLEY.**—Aug. 13.—For Construction of Cant Clough Reservoir and Works in connection. Mr. E. Filliter, 16 East Parade, Leeds.

**CASTLEFORD.**—Aug. 9.—For Building Mission Church. Messrs. Perkin & Bulmer, Architects, Calverley Chambers, Victoria Square, Leeds.

**CHEPSTOW.**—Aug. 20.—For Building Petty Sessional Court. The County Surveyor, 2 Bridge Street, Newport, Mon.

**DARTMOUTH.**—Aug. 9.—For Reseating Townstal Church. Mr. Ashford, Churchwarden, Coombe, Dartmouth.

**GARSTON.**—For Building Mercantile Marine Offices. Mr. S. B. Worthington, Engineer, Victoria Station, Manchester.

**HALIFAX.**—Aug. 10.—For Rebuilding Excelsior Works. Messrs. Horsfall & Williams, Architects, Post Office Buildings, Halifax.

**HAMMERSMITH.**—Aug. 12.—For Booking Office and Extension of Platforms, Latimer Road Station. The Engineer, Paddington Station.

**HUDDERSFIELD.**—Aug. 12.—For Building Chimney to Woodhouse Mills (Bricklayers' Work). Messrs. John Kirk & Sons, Architects, Huddersfield.

**LONGTON.**—Aug. 20.—For Building Relief, Vaccination, and other Offices. Mr. E. Scrivener, Architect, Howard Place, Hanley.

**LUTION.**—Aug. 19.—For Additions to Foundation School. Mr. F. R. Kempson, Architect, Hereford.

**MULLINGAR.**—Aug. 20.—For Building Post-Office. Office of Works, Dublin.

**NETHERTON.**—Aug. 16.—For Foundations of All Saints' Church. Mr. C. J. Ferguson, Architect, 50 English Street, Carlisle, and 15 Dean's Yard, Westminster.

**NETLEY.**—Aug. 13.—For Building Board School. Mr. William Jurd, Architect, 10 Oxford Street, Southampton.

**NORWICH.**—Aug. 13.—For Building Mixed Board School. Mr. J. H. Brown, Architect, Lower Close, Norwich.

**OLDHAM.**—For Additions to Newbreak Mill. Mr. S. Stott, Architect, 3 Clegg Street, Oldham.

**PETERBOROUGH.**—Aug. 19.—For Building Dwelling-house, Westgate. Mr. James Ruddle, North Street, Peterborough.

**PONTYCYMMER.**—Aug. 13.—For Building Methodist Chapel. Mr. Edward Lewis, Pontycymmer.

**PORTH.**—Aug. 12.—For Building Engine and Purifying Houses, Chimney Stack, &c., at the Gasworks. Mr. E. S. Pike, General Manager, Gas Office, Pentre, Rhondda.

**PRESTON.**—Aug. 20.—For Construction of Dock, Tidal Basin, Locks, Diversion of River, &c. Mr. E. Garlick C.E., 33 Winkley Square, Preston.

**SWADLINCOTE.**—Aug. 9.—For Extension of Market Hall Premises. Mr. James Nixon, Architect, Church Gresley.

**SWALWELL.**—Aug. 11.—For Building Paper Mill. Mr. J. Henderson, jun., Architect, 16 John Street, Sunderland.

**THURSBY.**—For Additions to Board School. Mr. James Leslie, Architect, 27A English Street, Carlisle.

**TYLORSTOWN.**—Aug. 11.—For Building Methodist Chapel. Rev. W. Jones, Ton Ystrad.

**VAUXHALL.**—Aug. 20.—For Building a 40-quarter Brewery. Messrs. H. Stopes & Co., Architects, 24A Southwark Street, S.E.

**WALSALL.**—Aug. 23.—For Erection of Farm Buildings, Brockhurst Farm, for the Corporation. Mr. Samuel Wilkinson, Architect, Town Clerk, Bridge Street, Walsall.

**WAKEFIELD.**—Aug. 15.—For Building Villa Residence, Boundary Walling, &c. Mr. Fred. Simpson, Architect, Southgate Chambers, Wakefield.

**WARLEY.**—For Building Barn at Gate Stoops. Mr. S. Wilkinson, Architect, Sowerby Bridge.

**WIMBLEDON.**—Aug. 23.—For Building Press House, Cake Shed, and Plant for Treatment of Sewage Sludge. Mr. W. H. Whitfield, Local Board Offices, Broadway, Wimbledon.

**WORCESTER.**—For Building Passenger Station, Langley Green Junction. Mr. J. S. MacIntyre, C.E., 9 Dan's Yard, Westminster.

**WYKE.**—Aug. 12.—For Erection of Coastguard Buildings. Director of Works Department, Admiralty, Whitehall.

**YORK.**—Aug. 18.—For Restoration of St. Crux Church. Messrs. Fisher & Hepper, Architects, 16 Castlegate, York.

### TENDERS.

#### ABERDEEN.

For Excavation, Concrete, Mason, and Iron Works of Viaduct, from Skene Street to Baker Street, for the Town Council. Mr. W. Boulton, Surveyor, Town House, Aberdeen.

BISSET & SON (accepted) . . . . . £2,990 0 0

#### ASHTON-UNDER-LYNE.

Wharf, Harrow Road, Paddington, London, W.  
12 Elm Street, Gray's Inn Road, W.C.

**GRUNDY'S PATENT  
WARM-AIR  
VENTILATING FIRE GRATE.**

The novelty, superiority, and advantage of this patent  
consist in the heating surface being greater than any  
other Fire-grate introduced to the public. It is very  
simple in construction, and is made in the form of a Stove,  
the back of which is semicircular in shape, with gills  
behind and smoke-nozzle on top, all cast in one piece.  
The same can be attached to any design of a Register or  
Stove front. It is very suitable for schools, class-rooms,  
waiting-rooms, hospitals, offices, dormitories, and dwelling-  
houses, from the cottage to the mansion. Design and  
specification post free on application.

**TESTIMONIALS.**

"9 Victoria Chambers, Westminster, S.W.

"June 10, 1881.

"SIR,—I have much pleasure in testifying to the  
efficiency of your patent Warm-Air Fire Grate. It has  
been very successful, and given every satisfaction where I  
have used it.

"Yours, &c.

"JAMES WEIR, F.R.I.B.A.

"To Mr. Grundy."

"Baptist Chapel, Clapham Common, London. Richard  
Webb, Pastor, 10 Grafton Square.

"February 15, 1884.

"DEAR MR. GRUNDY,—I have pleasure in testifying to the  
excellency and efficiency of your patent Fire-Grate. It is  
the most charming invention for heating a large room I  
have ever known. I shall have pleasure in showing it to  
anyone who wish to have their schools or rooms pleasantly  
and efficiently heated."

Apply to JOHN GRUNDY, 30 Duncan Terrace, City  
Road, London.

SPECIALLY ADAPTED FOR WAREHOUSES, SCHOOLS, AND PUBLIC BUILDINGS.

CABLE LIGHT

The Patentee begs to call particular attention to the great strength of this construction. The Bars and Bosses, being of malleable wrought iron, form an exceedingly firm joint at the intersection of bars. They are durable, and of light appearance, the Bosses being small and not unsightly. They can be made at very short notice, and at the price of an ordinary cast iron sash.

PRICES UPON APPLICATION.

CABLE LIGHT.

CLOSE BAR SASH (obviating use of Window Guards.)

ORDINARY WAREHOUSE AND SCHOOL SASHES.

VENTILATOR

Back view of Boss, full size.

Section through Boss, full size.

These can be glazed flat, like ordinary wooden sashes, without the corners of the panes being clipped off.

Front view of Boss, full size. Obscuring no appreciable light.

**THE GREATEST EXHAUST VENTILATOR IN THE WORLD.**

Admitted by the profession to be the only perfect one ever invented. It is guaranteed to be proof against draught under any circumstances. It is so constructed that all wind entering the head is converted into an upcast, and so forces out the vitiated Air, Steam, or Smoke. From one to one hundred rooms can be ventilated by one Exhaust, a means applicable to no other Ventilator. It is suitable for a Single Room, or any large building such as Offices, Public Halls, Churches, Hospitals, and Infirmarys; in fact, from a Soil Pipe to a Whole Mansion.

Working Models can be seen and tested by any expert; also our system of Extracting Steam and Smoke from Railway Tunnels, and Sewer Gas from Sewers, &c.

SOIL PIPE

**EDGAR ALDOUS & SON**

(Sole Inventors and Patentees),

18 QUEEN'S ROAD, PECKHAM.

**EASTWOOD & CO. (LIMITED).**

LIME, CEMENT, AND BRICK MANUFACTURERS.

**SHOEBURY, COWLEY, & KENT BRICKS IN ANY QUANTITY DELIVERED ALONGSIDE.**Shoebury Malm Facings and Paviers.  
Stourbridge, Welsh, and Newcastle Fire Bricks, &c.

Glazed and other Drain Pipes.

Dutch, Adamantine, and Red English  
Clinkers.  
Red and White Suffolk Bricks.  
Greystone, Blue Lias, and Chalk Lime.

Laths, Plaster.

Moulded Bricks of all kinds.

Red, White, and Black Rubbers.

Broseley and Yorkshire Roofing Tiles.

Ridge Tiles, Terminals, &amp;c.

Staffordshire Blue Bricks.

Chimney Pots, Slates.

Hair, Sand, &amp;c. &amp;c.

**PORTLAND CEMENT**

(WELLINGTON BRAND) of Unsurpassed Quality.

Sole London Consignees of Messrs. Gibbs &amp; Co.'s (West Thurrock) PORTLAND CEMENT, and the LUMLEY GLAZED BRICKS.

BRICKFIELDS:—WEST DRAYTON, MIDDLESEX; SITTINGBOURNE, KENT.

WHARFS:—

WELLINGTON WHARF, BELVEDERE ROAD, LAMBETH.  
CANAL BRIDGE WHARFS, OLD KENT ROAD, S.E.  
CHELSEA WHARF, LOTTS ROAD, CHELSEA.KENSAL GREEN, HARROW ROAD.  
VICTORIA WHARF, MORTLAKE, S.W.; and  
BLACK HORSE LANE, RICHMOND.

# The Architect.

## ACADEMICAL PLAN.

HERE are necessarily few, even amongst the small number of those that are professionally well acquainted with the language of architectural drawing, who can be trusted to pronounce an off-hand opinion upon the plan of a large and intricate building. As regards what are called elevations in whatever form—barring, of course, the artifices of draughtsmanship—everybody may be expected to read their effect pretty freely who has learnt to read them at all, and those who understand them well can read them with the utmost rapidity and with perfect certitude. Sectional drawings, also, are little, if any, less quickly understood. But plans—except in the single instance, perhaps, of a church of highly monumental character—are always more or less difficult to grasp at a glance, even as regards their *generalia*, to say nothing of their multifarious particulars in the various degrees of detail. It is plain, indeed, that the language of plan-drawing, although technically the same geometrical projection as the rest, is in its effect a language by itself, every line of which, to be thoroughly understood, requires alike the master's hand in the designer and the master's eye in the critic.

Thus it is, in the case of any competition of intricate architectural designs, that the plans are scarcely ever understood except by two classes of persons, namely, the rival competitors and the professional judges. And thus it is further that in so many instances the complaints of competitors who have been unsuccessful are found to turn upon the theory that, even by the professional judges, the merits of plan have not been sufficiently considered. In fact, it is scarcely too much to say that, beyond a certain point of complexity, no one but a competitor who has himself gone laboriously through the entire process of contriving a set of plans for the subject in hand will be capable of reading the collection of designs of plan with sufficient ease to compare together their real merits—real merits, indeed, as distinguished from those that are fictitious and indeed deceptive. In the case of a church, to which allusion has already been made, an experienced ecclesiastical architect can spot in a moment a plan of singular merit, for the simple reason that the subject is so entirely academical. His mind is stored with examples, rules, principles, and reasons, and his admiration answers at once to the call of memory and understanding. The science of plan-design in this field has arrived at that ultimate simplicity which is the end of all scientific development, and the expert intelligence is therefore thus clear and decisive. So also with the case of a high-class residence. Putting aside certain little pleasantries of the moment in Queen Anne plan, which amuse the æsthetes of the day, but cannot be recognised in any way as of permanent value, the arrangements of a good English house, whether in town or country, are thoroughly understood and accepted, subject to the law of development but no more. To an experienced eye, therefore, the comparison of a number of plans of this class, or the discernment of the merits of any single design, is quite easy, and the quick discovery of demerits more easy still. But here the subject is not academical in the same sense as the arrangement of the church; inasmuch as there is a certain identification of the academical character in domestic plan with the element of Italian regularity, as distinguished from that Gothic irregularity which modern English people may be said almost always to prefer in their houses. The French houses are in this sense academically planned, and the consequence is, as the English say, that they are exquisitely devoid of comfort. Let that pass, however, as a mere illustration; and perhaps a better illustration still is to be obtained by looking into the “*Vitruvius Britannicus*,” and comparing the best English domestic plans of the eighteenth and early nineteenth centuries with the general character of the really good examples of our own day which occasionally appear in the professional journals. The unanimous verdict must be that the newer houses are disposed throughout with reference to principles of mere occupation,

whereas in the older ones occupation has to accommodate itself as it best can to principles of an academical sort. But it cannot be denied all the while that those older plans are vastly more attractive to the eye as plans. They are symmetrical, regular, stately, classically artistic, compact, perhaps commodious, refined, and elegant. But as a fact, nevertheless, as their occupants know too well, they are inconvenient and uncomfortable, their compactness a snare, their commodiousness a delusion. Here academical plan is a failure.

These observations may now enable the reader who happens to be not an expert in plan to entertain a shrewd suspicion that in other subjects of design generally—monumental works always excepted—an academical plan may be an attractive deception. A public library or museum, or a suite of picture galleries, we may take leave to call quasi-monumental, if only on account of the contents; so also a prison or a workhouse, and even a public school or a college, must display a primary symmetry of its own in the arrangement of its plan. But when we come to such a subject as a great group of public offices of business, the critic ought not to be deceived by academical symmetries, but indeed ought rather to become alarmed when such spurious attractiveness of plan is apparent at first sight. If the integral divisions of accommodation were, as mathematicians say, equal and similar, then, of course, their disposition would exhibit corresponding equality and similarity. But this is never the case, and the equality and similarity which so charmingly run over a highly-skilful academical plan really indicate that the accommodation is compromised to meet the symmetry—a condition of things which in fact is more or less palpably manifested in the great majority of public buildings of the class in question, all over the world.

What actually happens in the case of a competition of plans of this order may be described thus. Each competitor feels that he must *academicalise* his plan as much as he possibly can, if only for the sake of attracting the notice of academical criticism. He is familiar with the observation which comes to be made invariably by professional observers, to the effect that a certain design is distinguished by “the excellence of its plan,” or another by the inferiority of its plan. He knows that this means pretty much the same thing as the approval of one for its “carefully-designed elevation,” or the disapproval of another for its want of such careful design. These are days in which people read as they run; and in competitions the design which fails to be read running has only its author to blame for being not read at all. Spurious academicalism of plan, therefore, becomes one of the artifices of the competition system, and the fact cannot be helped.

What happens, on the other hand, when an expert designer of internal arrangement has the task entrusted to him of devising a large and intricate plan without competition, is quite a different thing. He may very likely begin, and go on, with the hope that his plan will “look well” when completed; for indeed he knows, as others know, that this will secure for it that superficial approbation which is always a consideration with the best of us. It may be admitted, also, that in order to promote this end he will lay out his general scheme from the first with an eye to shipshape disposition as a rule of his work, guiding himself perhaps by precedents, and acknowledging the virtue of system in every way. He will even be prepared in the abstract for the necessity of compromising matters here and there for the sake of system. But, granting all this, he will proceed to the development of his arrangements in detail with a freedom from restraint which is invaluable. Clearly understanding as he does that the eventual criticism of his arrangements will be between himself and his clients privately, and that, in the unrestricted explanations which will take place, it will be a hard task to persuade careful practical men that the conveniences of occupation should be sacrificed to the prettiness of a plan, he will not scruple to make the arrangement take whatever form necessity demands, irregularities of cause producing irregularities of effect very much as they may. A plan so devised will not be an academical plan on paper, but it will be a thoroughly well-organised plan in execution.

It ought always to be borne in mind in designing such a plan that each room is an empire in itself, with its fixed dimensions of necessity, its fit arrangement of door, window, fire, desk, table, and whatever else; in short, its one proper disposition of everything just as if it stood alone. Thus, when an apartment is catalogued in competition particulars to be, say, 250 superficial feet in area, it is not to be supposed to be

an indifferent matter to the occupant whether it is made 25 feet by 10, with a window at one end and the fireplace and door at the other, or 17 feet by 15, with left light, fire in front, door in the right corner, and ample space all around for the transaction of business in a businesslike way. Again, when there are a dozen or more corridors in a building, floor over floor, all the same hundred feet long, and all exactly alike, what is the value of this except on paper, unless the business to be transacted be something like that of a penitentiary?

The true test of merit in a plan of intricacy is undeniably this—that every individual apartment shall, when completed, be as far as possible perfect in itself as viewed from within itself, and its relations to all other apartments also perfect, as if it were the centre of the whole. This is better than all the academicalism in the world; it is the true organisation of a building as compared with the fallacious prettiness of a paper drawing.

### ART AS FORCE.

THOUGH the present age shows unprecedented ability for talking about art, it seems scarcely to have made up its mind as to what art really is. A number of contradictory theories about it may be met with every day. There is, for instance, the utilitarian theory, according to which art simply means physical usefulness. A treatise was published some years ago in which this theory was applied with much labour and ingenuity to architecture. The writer took as his chief example Salisbury Cathedral, and tried to prove that the beauty of every part, down to the smallest moulding, simply arose from its fulfilling admirably its constructive function. The buttresses, he argued, were artistic only because they were well designed to resist thrusts, the columns because they were well calculated to support pressure, and the roof and spire because they were well shaped to throw off snow. Such a book might have been written by a lover of art as an apology to a materialistic age for his favourite object. "You want nothing that is not useful," he seems to say; "nothing that will not in some way help to feed or clothe or shelter you. Very well: I am prepared to prove that this is precisely what art will do for you, and that it will do it all in the most perfect way. When you see this, I hope that instead of despising art any longer, you will begin to encourage it." It was just so, according to Mr. BROWNING, that ANDREA DEL SARTO talked to his worthless wife, and begged her to tolerate his pictures because pictures meant money, and money meant fine clothes and feasting.

Much more generally believed in is the educational or quasi-scientific theory. According to this, art simply consists in a true representation of the facts of nature. Where these facts are properly represented we are assured there is real art; where they are not represented, or represented without complete accuracy, there is no art at all. Exact imitation, according to this doctrine, is everything. But if this be true, why spend an infinity of pains in copying things that we can so easily see for ourselves? The landscape painter, in particular, should not waste his time on scenery that is within everybody's reach. If he can paint something rare or almost inaccessible—the eruption of Krakatoa, or the "sea of ancient ice"—and so show us what we could never have seen for ourselves, there will be a reason and a justification for him. Not so, on this theory, if he paints in Cornwall or in Cumberland—much less if he gives us Richmond Hill or Hampstead Heath. Like AGESILAUS, we do not want someone to counterfeit a nightingale: we can hear the nightingale herself. We do not want a costly picture of those places which we can see over and over again with little trouble, unless there is something in the picture which the places themselves cannot give us. It is not enough that it should be true: to be a work of art it must be something more. A skilfully-taken photograph may, in this narrow sense, have more truth in it than any picture—a catalogue or an inventory more truth than any poem; but truth alone does not bring things like these into the category of art.

Somewhat allied to the last—as proceeding from the same desire to show that art is food for something which the duller can appreciate—is the moral theory of art. This judges every work by its tendency, and pronounces that work not merely good or bad morally in consequence of this, but good or bad as art. Every picture and every poem, on this theory, should have its story to tell, and its lesson to wind up with. It should

be, in short, what HOGARTH'S *Idle Apprentice* and CRUIKSHANK'S *Bottle* are in painting; and what every "novel with a purpose" is in literature. How popular this class of work is any exhibition will prove, and it is always most popular with those who are most incapable of distinguishing the admirable from the worthless. The end, with them, sanctifies the means, and they overlook the badness of the picture in the excellence of its object. It is not surprising that the reaction from this theory has produced an exactly opposite one, and that those who protest against confounding art with morality sometimes seem to confound it, themselves, with the opposite of all that is moral.

There is one thing, at least, that may be said of all these theories. None of them really define art, or tell us how to know it when we see it. All they do is to indicate certain uses to which it may be put. Art may be applied, for instance, to severely practical construction, and applied so as to add hardly any new features to those which necessity had already called for. In the case of Salisbury Cathedral, which the first or utilitarian theory puts forward as an example, it may be granted that structural wants had already demanded the vault, the buttresses, and the columns. But it is not in the satisfaction of these structural wants that the art consists. These wants would have been perfectly satisfied if the nave had only been 30 feet high instead of 70 or 80, if the columns had been round instead of curiously clustered, and if the buttresses had been destitute of a moulding or a chamfer. And though art in this case may not have added many unnecessary features, it has utterly transformed the proportions of the necessary ones, thus making the whole church more than twice as lofty as bare physical utility would have dictated. Art may be applied, again, to exact representations of the facts of nature, and may group together into an effective whole a number of studies showing the way in which clouds drift and stems grow and leaves expand. But it is not in the exactness of the copying that the art of the picture lies. If we could fix for ever the reflection of each cloud and stem and leaf in a mirror, we should have far more exact copies, and yet no art at all. The art lies in the choosing of this detail and the excluding of that, and in the proportioning and arranging of them all; so that out of many disconnected parts there may finally issue one organic whole. And this same process may be applied to forms and colours which do not image those of nature, as well as to those which do. There is art in the decoration of the mosques at Cairo, though their designers rigidly abstained from copying anything in heaven or in earth. There is art in the fighting centaurs of the Parthenon, and in the grotesques of many a Mediæval church. We may regret sometimes that the art has not been put to better use and employed on more worthy materials; but there it unquestionably is: and so we learn that the second theory, like the first one, tells us not what art is, but only what, in the theorist's opinion, artists ought to do with it.

It is still more obvious that the essence of art is not to point a moral and adorn a tale, whether that tale be good or bad in its tendency. This, like the rest, is only one of the purposes to which it may be applied. But what is this elusive power which so many theorists have tried to seize and examine, and which has only left its garments with them and fled? After so many failures, he must be a bold man who would attempt a full definition. Art is not physical utility, though the physically useful may be transformed into the artistic. Art is not the mere statement of truth, though statements of truth, by pen or pencil, may be made into a work of art. It is not the essence of art to teach, though teaching is one of the many things it may be set to do. People say at times that the age of painting is really over—because the object of painting was to teach, and teaching is now done by books. The age of signboard painting is doubtless over. When hardly anyone could read, every tradesman put up a sign at his shop door instead of a name, and much of the art of the Middle Ages concerned itself with what were, in reality, only signboards of a higher kind, applied to religious and ecclesiastical uses. But it is not the mere communication of facts that gives its value even to painting, much less to arts like music and architecture, and to the still higher one of poetry. Art is energy, not direction; an impulse, not a guide. By itself it may be a power to calm or a power to arouse; it depends on the use that is made of it what kind of calm or what kind of action it may tend to produce. Whatever else art includes, it is of its essence to communicate force—not

through the medium of assertions or reasons or inferences, but by its own direct action. It needs to make no statements, it calls in no aid of logic: it simply appears, perhaps in a line of poetry, perhaps in a strain of music; and the force that was in the mind of its maker is straightway communicated to other minds, no matter how far away in time or space. It is by its ability to do this that art announces itself, and the power to do it may be regarded as the one essential element which is traceable under all its infinitely varied forms. Art is force, and the higher the art the greater its effect to modify—either in the direction of calm or of action—the minds which come under its influence.

### HOSPITAL CONSTRUCTION.\*

THERE are some facts recorded in Dr. MOUAT's essay on "Organisation of Medical Relief in the Metropolis" which are by themselves sufficient evidence of the necessity of a better system of hospital construction—if one can be devised. The normal death-rate in the London hospitals actually amounts to nearly one in every ten of the patients admitted, being 9 per cent., or 90 per 1,000. In the Prussian hospitals the mortality is a little less, as it is 88·8 per 1,000. It is found that, on an average, there are 100 deaths every year in the London hospitals from pyæmia or blood-poisoning, and in the majority of the cases the origin of the disease is to be traced to the hospital. In the very first year it was opened there were 19 deaths in St. Thomas's Hospital from that cause. Out of 110 fatal cases of blood-poisoning in the hospital 6 only arose outside, and of 485 cases of erysipelas 332 originated in the wards. Guy's Hospital in one year had 38 deaths from pyæmia. There seem to be no returns of the number of cases which were not fatal, but it may be assumed that they amount to a large number.

By recognising the hospital itself as a factor in the mortality of the patients, a revolution in the construction became inevitable. It may be doubted whether the builders of the older hospitals ever gave a thought to such a contingency as blood-poisoning; life or death was supposed to depend on the skill of the physician or surgeon and the constitution of the patient. Fifty years ago there were very few doctors who would venture to say that the blood could be a seat of disease, and architects are not to be blamed if they were no wiser than the doctors. Now a very different theory of life is held, and one might almost venture to say that the hospital of the future will be planned mainly with a view to the prevention of blood-poisoning. If that end be secured, it may be assumed that very little else is needed to form a perfect hospital. But the task is so difficult that some physicians have declared that satisfactory conditions are an impossibility in an hospital if it has been in existence for a longer period than five years, and that the periodical destruction of the wards by fire is a public duty. The Continental doctors are probably more advanced than their English brethren in their views on this subject; and the second division of the volume, on Hospital Construction, by Dr. MOUAT and Mr. SAXON SNELL, was therefore wisely assigned to a description of some of the hospitals in France, Germany, and Italy.

The first building described is the new Hôtel-Dieu in Paris. This building, which was opened in 1876, from its position is known to most visitors to that city. It stands near Notre Dame, and as it is bounded by the Seine, the parvis of the cathedral, and two wide roads, the site is fairly good. For the land, which has an area of over five acres, 720,000*l.* had to be paid. The buildings cost 687,690*l.* and the furniture 13,682*l.* As there is accommodation for 566 patients, the total cost per bed has been 2,510*l.* But, in spite of its cost, the hospital has been condemned by many doctors. One said it was a magnificent structure and a detestable hospital. What doctors want are simple, plain, quiet hospitals, which could be pulled down, renewed, removed, or otherwise dealt with as the necessities of the hour might require. A second authority said that the tent was the best type of hospital, then the hut, and lastly, the block hospital, that is, supposing the blocks were entirely isolated and exposed to the action of the air on all sides. The Hôtel-Dieu, being united by a central "corps de logis," was doomed to be a hot bed of infection should an epidemic arise in Paris. A third doctor said that the building

is so utterly bad it is impossible to turn it either into a large or a small hospital. Finally, it was resolved at a conference that the new hospital is so constructed as to be absolutely contrary to the fundamental principles of sanitary laws. A dozen years have elapsed since the evils inherent in the Hôtel-Dieu were first described, but it must be said that there is little to show how far the prognostications have been realised. As a concession to the opposition, the building was never carried up to its full height, but there appear to be more patients in the wards than were originally proposed. The objection to the hospital is that it is not on the plan suggested by TENON, a French surgeon, who died in 1816. One on that plan has been built at Menilmontant, near the cemetery of Père Lachaise. It has four main double blocks or pavilions, which are each four storeys high, and are connected at either end by corridors. But the floor space per bed is only about 107 superficial feet, while in the Hôtel-Dieu it is 125 feet, and the cubic space is proportionately less. The flooring consists of hollow brickwork and concrete, with timber joists and oak boarding beeswaxed and polished. The walls are finished with lime and powdered marble, brought to a polished surface like scagliola. Angular corners are supposed to be refuges for disease germs, and in the Tenon Hospital "all the angles formed by the walls one with another, and with the plastered ceilings, are rounded to a radius of about 6 inches." The sanitary arrangements of the hospital are not, however, up to the English standard.

If sharp angles are dangerous, there is much to be said in favour of the plan by M. TOLLET, which has been adopted largely in France. It was exemplified by drawings which were shown at South Kensington a few years ago; but then it did not attract much attention. The principle is that the section of a ward should be of an ogival form or pointed arch, and thus there is an impediment to the accumulation of disease germs. Air can circulate freely, and it is easy to cleanse or fumigate the interior. Wrought-iron rolled joists are placed about five feet apart, and are bent to suit the contour of the roof; the spaces between them forming the walls are filled in with brickwork, and the upper or roof portion with tiles, brick, or concrete. The whole of the inner surface is coated with plaster and finished with three coats of oil paint, the lower part being sometimes of lime and powdered marble with a floated surface. The system gives a large cubic space, the wards being 18 to 20 feet high, and the cubic area from 2,000 to 2,500 feet per bed. The cost of the system may be judged from the St.-Denis Hospital. It provides for 166 patients, and the building alone cost 40,000*l.*, or about 241*l.* per bed. But at Montpellier M. TOLLET is constructing an hospital where the cost for the freehold and building is not expected to be more than 114*l.* per bed. The question will be asked whether the system is deserving of approval. American experiments seem to prove that above 12 feet in a room there is little or no movement in the air except towards the outer ventilators; and as M. TOLLET's wards sometimes have an extreme height of 25 feet, the upper space may be considered a disadvantage. Mr. SAXON SNELL is of opinion that none of the buildings which have been constructed by M. TOLLET come up to the principles explained in the inventor's writings and plans.

There is apparently much to be said in support of the advantages of curved over plain surfaces for hospitals. In the new hospital at Genoa, founded by the Duchess GALLERIA, and which is to cost over three hundred thousand pounds, the principle has been adopted in a somewhat remarkable manner. We are told that "the ceiling over each pair of beds is vault-shaped, and is supported entirely independently of the floor, in order, it is said, that if the physicians should be at any time of opinion that disease germs have permeated the plaster, these ceilings could readily be removed and danger averted." Professor JOHN MARSHALL a few years since published a pamphlet in which he advocated circular wards, and a sketch of an hospital on a similar plan was submitted by Dr. BURDON SANDERSON to the Commission on Small-pox and Fever Hospitals. There would be twelve beds in a ward, arranged around a central chamber or shaft, each bed having a floor space of 178 superficial feet, and an air space of 1,780 cubic feet. Objections were raised against the system. It was said that in the circular wards in Antwerp and Baltimore the beds are arranged against the outer wall, and the patients are not disturbed by the light from the windows, and that Dr. SANDERSON's central shaft was too large; but both objections, if valid, could be got over.

\* "Hospital Construction and Management." By F. G. Mouat, M.D., F.R.C.S., and H. Saxon Snell, F.R.I.B.A. Published by J. & A. Churchill & Co.

Our time is, as regards hospital construction, one of transition and therefore of uncertainty. The science of medicine is being affected by new discoveries, which have their influence on hospitals. Many of the defects in buildings take their rise from the convenience of the doctors obtaining more consideration than the well-being of the patients. In England it is a great advantage to a physician when he is attached to a hospital; but the time he can spare for visits becomes limited in proportion to his success, and it is therefore necessary that facilities should be given for the examination of several patients in a short time. The wards are accordingly made large so as to hold a vast number of beds, although smaller wards would be safer for the patients, and more conducive to their ease of mind. Another reason for large wards is the clinical teaching, that is to say, patients must suffer for the sake of students. A third is cost of management, which is supposed to be in favour of the existing system. The ideal hospital would be one in which the patients' interests were paramount, and would contain a greater number of smaller divisions than is now adopted, and which might be sacrificed occasionally without much compunction. This plan is not so far from the French doctors' "tent" and "hut" as might at first be supposed. The authors of "Hospital Construction and Management" know the defects of existing hospitals, and we hope that some day they may have the courage to describe them. Their book is useful, as suggesting what efforts are being made to get over the difficulty of constructing an hospital that will be an auxiliary to a patient's recovery, without any interference with the established organisation of the medical and other attendants.

### THE BLENHEIM PICTURES.

THE following communication is from Mr. J. C. Robinson, F.S.A.:—The public in general and the Government are agreed that a selection from the Blenheim pictures ought to be acquired for the nation, but hitherto it has not seemed possible to come to terms with the Duke of Marlborough or his advisers. There are two principal points to be considered in this negotiation—first, the particular pictures to be chosen, and, secondly, the price to be paid for them. The advisers of the Government seem to have done their best to agree with the duke as to the pictures to be purchased, and they have made splendid offers for the selected works. I believe it is a fact that 120,000*l.* was in the first instance formally offered for three pictures—the Raphael *Holy Family*, the equestrian portrait of *Charles I.* by Vandyck, and the *Garden of the Hesperides*, by Rubens—but this sum was unhesitatingly declined. Another offer was then made of 80,000*l.* for two of the pictures—the Raphael and the Vandyck—but this was also refused. Nevertheless, it is the opinion of the most competent judges that these offers were amply sufficient, and that the duke was not well advised in declining them. At this stage of the matter it appears to me that discussion would be advantageous, for it may be assumed that there is a desire on both sides that the negotiations should not drop through.

The Marlborough family are in possession of a collection of pictures to which great celebrity and historic repute attach. Among them are a certain number of works of the very highest value, but the bulk of the collection consists of comparatively unimportant specimens. This being so, I apprehend that the best plan would have been to have brought the entire series to public auction. If that had been the course adopted, the nation and other powerful competitors being in the field for the choicer works, they would probably have commanded prices beyond all previous experience, while for the more numerous residue the prestige of the occasion would have attracted wealthy yet uncritical buyers from all parts of the world, eager to purchase good, bad, and indifferent pictures alike at unheard-of rates. This, indeed, is exactly what happened at the Hamilton sale two or three years ago.

The Duke of Marlborough and his advisers, however, seem to have had other views. Apparently they thought it would be possible to sell the principal works, sixteen or seventeen in number, for what may really be characterised as a fabulous lump sum, and to retain the residue for the decoration of the historic mansion as before. But the prices put upon these selected pictures were vastly beyond even the most exaggerated estimates formed by the various experts, both English and foreign, who examined the pictures for different clients. The national authorities, properly as I think, declined to entertain the purchase of the entire selection on this footing, and, although it is unwise to prophesy unless one knows, it certainly appears to me highly improbable that any infatuated Cressus will come forward to take these pictures on the stipulated terms, or anything like them.

Undoubtedly, in electing to pick and cull two or three pictures

only from the collection, the Government should have been prepared to pay a greatly enhanced price for them, for such a first choice would be sure to prejudice to some extent the sale of the remainder; but this enhanced price they may be held to have tendered, for it seems inconceivable that any other Power would have been found to offer an average price of 40,000*l.* each for the three pictures selected. Now, as to the pictures chosen, one of them, the Raphael, is unquestionably an unique and all-important work, but the same can scarcely be said of the other two. This country contains many other pictures, by Vandyck and Rubens, of equal importance. We have, indeed, just seen at the Leigh Court sale a magnificent Rubens—*The Conversion of St. Paul*—to my mind a work quite as valuable as the *Garden of the Hesperides*—fail to find a purchaser at a fraction only of the price put upon the Marlborough picture. As to the Vandyck, this is a huge gallery picture, doubtless of very high merit, but its size alone, as in the case of the Leigh Court Rubens, greatly detracts from its sale value, inasmuch as it would be difficult to find any private purchaser for it. Moreover, there are already two great equestrian portraits of Charles I. by Vandyck accessible to the public. These are the splendid picture in the Royal collection at Windsor Castle, a work certainly in no way inferior to the Marlborough picture, and the fine replica of the same picture at Hampton Court. On the whole, the nation could afford to wait, or even to do without this picture.

On the other hand, there are two pictures by Rubens in the Blenheim collection, of transcendent merit, which the nation has not yet taken into account. These are the full-length portraits of Rubens and his wife, and that of his wife alone. This last-named picture is certainly an incomparable masterpiece; in my own opinion, indeed, from its intrinsic excellence as a thing of beauty, good for all time, appealing to all alike in the same intelligible voice, this picture is even more precious than the somewhat archaic Raphael, and I cannot but think that its acquisition by the nation should be made a *sine quâ non* in any further negotiation. Moreover, as the other Rubens portrait picture is of very similar aspect, and scarcely less valuable, it could probably be better spared from the Marlborough collection than even the *Garden of the Hesperides*.

Meanwhile, it would be very desirable in the public interest, and it could only tend to the advantage of the owner, if the Blenheim pictures were again made accessible to visitors. It would be a great mistake if the interest now manifested on all sides were allowed to cool. Many unforeseen things might happen to prevent the renewal of negotiations for the nation, and a general feeling of distaste and depreciation might not impossibly follow as a reaction from the exalted estimate which has been formed of the Marlborough pictures.

### THE TEACHING OF DRAWING AND OF COLOURING AS A PREPARATION FOR DESIGNING AND DECORATIVE WORK.\*

By A. F. BROPHY.

IN the following paper I will try and give the most direct method of teaching a student how to draw, and as to colouring, the best method of receiving instruction from nature.

Drawing is all important—to draw is to create. Drawing is the body and soul of art; colour but the garments an artist's creations wear.

Every field and hedgerow presents numerous suggestions for arrangements of colour, from the most varied contrasts to the most subtle harmonies, all beyond the definition of a rule, and defying classification in the infinite varieties of their blending hues. Still, every colour is obeying the great law of fitness of tone for its position—a lesson the very best to govern all coloured schemes of decoration. Colour in decoration is entirely subordinate to drawing. A student taught to draw, whose observation has impressed him with colour, and whose education has been to observe the life, character, colour, and forms of what he sees around him in nature, has prepared a mind which a practised teacher can readily utilise. From the very first entry of the elementary student into the class, you must try and impress him with the idea that every drawing, even his first, is a complete work in itself—a training to the hand and mind—a work executed with care and interest, one in which the student not only receives a lesson in the perception of form, a lesson in technique, but one in which you give him an opportunity of exercising his invention. This idea should always be kept before him, that no matter what the material is in which he happens to be a worker, it will entirely depend upon himself, upon the conception of some idea of interest brought into his scheme of decoration or ornamentation, whether such work be a work of art or not. Upon these lines only can any scheme of teaching that pretends to help our industries be successful. You must love your labour to do good work,

\* A paper read at the International Conference on Education on August 6.

and you must think your work worthy of all your labour, and capable of becoming a work of art to love it. I think there is no greater mistake or one more calculated to injure our industries, than that a system of teaching should be adopted in technical schools that profess to educate decorative artisans, which would elect to make all students try for what may be called the fine arts, making picture painting the climax of their ambition, sacrificing the many for the sake of the few, who could transfer their work executed in the schools from their easels to the walls of an Academy exhibition. The mischief lies in the fact that those who would return to decorative industrial work would do so broken-hearted, labouring under the stigma of failure. They will never make good artisans; their heart will not be in their work, they will hope for the day when their attempts at pictures, and the works of their more talented fellow-students, taught under the same system by the same masters, will once more be side by side on the walls of an exhibition as they were in the days of their studentship in the schoolroom.

When our artisans are true to their name, art-workers, and when the public are educated so that they appreciate their efforts, then we may hope for art-work; that produced to-day will be fit to place side by side with the best of the old masters in our art museums. This can only be achieved by the simultaneous education of both classes—those who make and those who buy. The purchasers, or what is called the non-industrial class, should have lectures delivered to them illustrated by examples of the best art workmanship in different materials. I think a great impetus would be given to this if our art masters throughout the kingdom were allowed to reap the same benefit for teaching art design to the non-industrial as they do to the industrial class. I consider the policy short-sighted that encourages one and not the other. It is the educated man who supports good art, not the ignorant. I know of one industry that has a lecturer who takes with him from one town to another the best samples of old lace, and lectures to both those classes, the industrial whom he visits in their work-room, and the non-industrial, to whom he explains by illustrated lectures the art and history of lace, showing by reference to good old examples their beauties of design, thereby sowing the seeds of knowledge which have already taken root, and promise to blossom into commercial prosperity.

To describe the teaching of drawing and colouring to a student who is to become a designer and decorator, which is the principal object of my paper, I will try and explain his progress step by step, the work which he will be required to execute, and the materials in which he will execute it, so that he may have an idea of what drawing is, and how to observe colour.

I divide a student's training into three periods: the elementary, the historic, and the practical.

The elementary class period I think the most important, because of the difficulties to be overcome in capturing the student's whole attention, above all things not allowing him to feel his first work is a grind at something that will prepare him for art work; he must feel that he is engaged in making use of a useful material, and about to develop a work which will show some of his own feeling. To accomplish this place before him an outline drawing of some simple form, directing his attention to what the copy is, an illustration of which he is to make a note; then tell him he is to sketch it the correct shape, when it will be corrected as to form. The best material he can use to do this is willow charcoal, because of the freedom of line and the ease with which you can both sketch and erase. When the form is declared correct you may teach him how to hold and use a brush. The student now exercises his own taste or fancy in covering the form in some colour or colours. This brings all the student's powers into play at once. He feels when the form is declared right the pleasure is in store to exercise his own judgment in selecting the colours, and the finishing with brush outline gets a completeness in his work that becomes with him a habit through his career; he even learns from his failures what to avoid; above all, he learns to finish his work.

The examples to use in this class are copies in outline of objects in the South Kensington Museum or other art collections, a description of which is printed on each copy, and if the object represented is a piece of ornament that illustrates a style of ornamentation, or specially marks a date, it is so stated on the example, so that the copy at once becomes a study for the hand, information for the mind of the student, and also from his being taught how to hold a brush and lay a tint, this becomes his first lesson in what may be called the technique of painting.

During this elementary period the student is required to attend class lectures in geometry and perspective—the geometry to instruct him in methods of striking out geometric patterns, and perspective to prepare him for the next step in his teaching, drawing geometric models.

The first group of models that is placed before the student should be so placed that it will be easy to point out the application of the laws of perspective just learnt. For the purpose of correction I have found the very best method to adopt is to have a large sheet of glass that can be placed between the student's eye and the group of models, of which a freehand study has been made. On the sheet of glass there is a correct perspective drawing in white outline. This will help to correct the freehand study,

and show by ocular demonstration the correctness of the perspective theory.

The student, in working from these models, in every case works in some material that is identical with one that has a place in the industries.

No time must be spent drawing or shading in a material that is used for the sake of school practice only. Why should not a student learn the art of light and shade in a material that he may have in his hands every day? I maintain there is no industry in which any artisan has to work in which you cannot find some material by which he can be taught elementary art from the beginning.

When, with a knowledge of drawing and painting in some material, the student leaves the elementary and enters the historic ornament class, the best examples of the different styles are placed before him, to both draw, colour, and paint in the same material as the original, if possible. The first thing is to explain to him the art or beauty of the example, where it was used, whether as a piece of decoration it stood alone, or whether it formed a background for some other object, because its position has determined its treatment ornamentally.

If the decoration be a scheme of ornament that by repeating one motive becomes a diaper, then its consequent breadth of treatment must be explained to him, the necessity of accuracy and exactness of the repeat, so that each one will register in its proper place, and the part that the spaces between the ornament play in the effect of the whole treatment should be pointed out.

In the study of historic ornament that refers to diapers, attention should be drawn to the fact that they are always subordinate, and take their places as backgrounds, that their design and colouring are suitable to their position—the design, by repeating one motive only, not calling for any special attention; and the colouring, by being in tones of one colour or in colours so nearly allied in value, giving great breadth of treatment that will not attract from any object in front.

The next step will be to copy ornament that often, in strong contrast with the ground on which it lies, is dependent on its contour for its beauty. This class of ornament, which stands by itself, is of a higher grade, and having in it an evidence of life or growth, must have its character explained in copying. The correct feeling of the ornament is only to be obtained by the student working in precisely the same way as the original inventor; consequently in correcting the work much more stress must be laid on the life and growth of the different parts—their character in the details being felt—than their relative exactness of size or proportion.

To explain this, the most important part of my system, I will take for example a piece of Italian arabesque ornament, with scroll and subject introduced. The student sketches in charcoal the size of the subject panel; then, in striking the scroll, he is allowed a slight latitude in the size, so long as he draws that scroll with the same grace and with the same feeling as the original. To exactly measure, or even measure in an increased or diminished proportion, to obtain by precise points the exact position, through which must pass all the details of this scroll, will be to prevent the possibility of the drawing having the same grace or elegance; the work will look laboured and cramped, lack the go or vitality of the original. No ornament gives such pleasure as that which seems done with ease. Time spent in obtaining mathematical exactness in free-flowing ornament is misspent. The sooner the pleasure of drawing ornament quickly is felt, the better.

The lectures in technique in this class must be carefully given, the amount of work or finish in the ornamentation applied to each material depending on the coarseness or fineness of texture; and the processes through which the object has to pass, illustrated by examples of good old work, should be shown the student, in which these qualities have not only dictated, but even created the style of ornamentation. Before leaving this class, I would have all students to feel the necessity, when studying from ornament, to do so in a material in harmony with the subject. To attempt to copy the large rich foliage of the Roman scroll with a fine wire line, or attempt to render delicate light and shade examples, except in light and shade, is bad practice.

With these lessons the student is now in a fit state to receive the instruction in the advanced class that will complete his training.

In this, the latter period, to which I have given the name of practical, I only wish to give this especial name, because here, by bringing the student face to face with nature, I want him to acquire that knowledge and creative power that will so store his mind with material drawn from the life, that the filling of a space with appropriate ornament becomes to him an instinct, and he has merely to be given some object whose manufacture he understands to beautify it, either with new beauties of ornament that will emanate from his own mind, or in applying ornament that has a known character or style, to so apply it as if it was originally created for the object immediately before him.

Here also the charms of nature's colouring—always varied, never an exact repeat, changed to suit every position—should be carefully noticed.

The student commences the study of nature by having placed before him a plant in flower. In a given time he will be required

to make this study. To feel its precise value as a scheme of colour, he will have to execute this on some neutral background, white for choice. In the drawing he will be instructed, above all things, to catch the growth of the plant, how the leaves and flower spring from the stem, and in drawing the flower, how the different petals spring from the centre. Let the brush with which he draws suggest this growth even in the drawing. Let him not stop for exactness of size. Time, which is important in the drawing of plant forms, will be lost; also, there is a risk of losing what is more important still—the feeling of life or growth. A flower, a little different more or less in size, can still have the correct character, so also with a leaf, or group of leaves. The student now has the scheme of colour that the plant suggests pointed out: how the stems with their leaves and their varying tones of green take the place of a harmonious background to the flowers; how these flowers themselves often suggest arrangements of colour. What can be more beautiful than that given by a pale yellow rose, with its various tones from pale to deep rich gold, the centre giving those few touches of purer and more positive colour that are just wanted to make the scheme complete without disturbing the harmony? Here is a lesson for application. Take the flower, a harmony in yellow. This by careful study reveals the fact that although the harmony is complete every tone of yellow differs; still yellow is felt throughout as the predominant hue or colour. From the flower alone an exercise should be insisted on, the two conditions of all decoration work being given as the bases, one in which it is required to design a panel as a background, with a repeat of the plant giving the ornamentation as an arrangement in yellow, the other exercise a decoration that, not forming a background, shall have to stand by itself—an ornamental treatment of the plant.

This practice will serve as better lessons in colours than attempting to make all decoration subject to a rule that insists on the presence of the primary colours in certain relative proportions, a rule which if carried out would condemn those beautifully decorative treatments, a peacock-blue room, a gold room, a grisaille plaque, or a Henry Deux candlestick, treatments all of which are both beautiful in design and colour. Any rule would have to change every time the conditions varied, which would give a rule for every particular condition or position in which a decoration was placed. This would end in nothing but confusion. The sense of fitness for its position seems to me the only general rule that can be laid down for all decoration, whether coloured or not. For example, you may want to give a cheerful or brilliant tone to what may be a dark or badly-lighted room; on the other hand, a room that is so constructed that the sun is continually there may want subduing. Again, you have some gems of art workmanship that you wish to show to the greatest advantage; the coloured scheme of decoration used behind these can be so toned that the eye is satisfied that nothing interferes with the objects on which you wish to be able to concentrate all your attention; or, again, you may want in some hall or passage to the principal rooms to make the ornament the complete decorative finish of that part. Here ornament that asserts itself by strong contrast, and is pleasant to the eye by its beauty and variety of line, is evidently the right one for the position. Yet these ideas can only be put as suggestions. The artist's mind must conceive and carry out what is evidently appropriate, suiting his colour to the requirements of its position.

The next step will be to acquire a knowledge of animal forms, their actions studied from life, so that the student can use them in what position in his composition he pleases. Now, versed in all the difficulties of the technique of the material in which he is working he approaches the study of the human form, that is, and should be, the crowning knowledge of every ornamentist, and without which he can never give to any composition that interest which awakens the emotions. I would have him first draw the extremities—life-size, or as near life-size as possible—filling in the bones and muscles to the different parts, then attempting whole-length figures, executed in a given time, varying the exercise by making small studies of the figures in motion. These studies should be painted in tones of one colour; that would make the exercise one in drawing alone, colour being used to carry this to its utmost limit. When the student can make a complete study of the human form from the life, I would place him before an antique statue, that he might work from an admitted perfectly proportioned figure; then, on his return to the life class, I would require him to execute drawings of draperies on the figure, always trying to finish his study in the one sitting, varying the practice again by endeavouring in rapid sketches to catch the movement of draperies on the figure in motion, aiming in all his attempts at perfect draughtsmanship. When a student can draw the human form, some exercises in composition should be given him, to be wrought out in monochrome. Where the figure is used, his composition should be so designed that the action which he wished to convey was evident in the composition; the principal lines or masses leading up to it to give the required impression in all its strength, sacrificing the details for the sake of breadth. The value of this quality has been the strongest argument in determining that the student must work in monochrome.

The lectures to this class should be on the forms of animals, their habits and actions (assisted by instantaneous photographs),

the anatomy of the human form, lectures on the different phases of the antique, also the impressions the best allegorical figures of the Renaissance give of action and repose. These lectures would be greatly enhanced by a supplementary course on the mythologies of ancient Greece, Rome, and Scandinavia, which, when understood, can be seized as part of a decorator's store, to add materials that would give interest and charm to his inventions. In this way we may hope to produce not only a designer but a decorative artist.

The highest art is that which contains the greatest thought combined with the greatest technical power.

In the many suggestions I have made for teaching drawing and colouring, I have kept within what I consider the true lines of instruction in what may be called technical art.

## VENTILATION OF WORKMEN'S HOUSES.

THE latest application which Messrs. Robert Boyle & Son have made of their system of ventilation is intended for workmen's houses and the houses of the poor. The inventors have long been of the opinion that if some simple and efficient ventilating apparatus could be devised at a cost that would enable it to be applied to even the poorest houses it would tend considerably towards the improvement of the public health in general. It is well known to medical men and sanitary officials that the pestiferous atmosphere which generally exists in the houses of the poorer classes is the cause of the majority of the diseases and fevers which haunt the more densely-populated parts of towns. This fact and the necessity of some economical system of ventilation were pressed upon Messrs. Boyle's attention ten years ago by Mr. Edwin Chadwick, C.B., but they were not in a position then to act upon his suggestions. They did not, however, lose sight of the question, and only waited until the public mind would be fully alive to the importance of the subject, when they could submit an improved system, with some hope of its acceptance. It is believed that the time has at last arrived, and the accompanying diagram shows the arrangement Messrs. Boyle propose to apply

for the purpose of securing a constant extraction of the foul air and supply of fresh air to each apartment without the slightest draught being felt by the occupants. The latter quality is essential, for it is a common experience that where ventilating openings are made, which admit of draught, they are at once closed and rendered useless as ventilators. A (see diagram) is a Boyle's Patent Self-Acting Air-Pump Ventilator, 16 inches diameter, fixed on the ridge of the roof. This ventilator, as is well known, continually extracts the foul air, and is entirely free from down-draught. B is a main shaft, 8 inches diameter, with divisional-plate in centre, to prevent the currents from the branch pipes striking each other and creating a swirl which would be injurious to the ventilation. CC are 5-inch diameter branch pipes connecting ventilator with  $4\frac{1}{2}$ -inch flues in the walls; D D are  $4\frac{1}{2}$ -inch diameter pipes connecting upper

rooms to branch pipes by means of 4-inch diameter holes cut in centre of ceilings; E E are  $4\frac{1}{2}$ -inch flues in walls communicating with spaces F F between joists and 5-inch openings in centre of ceilings, blocked on opposite side to flue G G G G. Air-inlet brackets, 10 inches by 5 inches by 3 inches, are fixed in the corner of each room furthest from the opening in ceiling, and about 6 feet from the floor. It may be frankly stated that Messrs. Boyle do not submit this system with any expectation of deriving a profit from the manufacture. It is introduced simply for the benefit of the working and poorer classes. The following description will suggest the amount of material and labour on one of the ventilators:—One 16-inch diameter Boyle's patent self-acting air-pump ventilator, made of galvanised iron and painted;  $1\frac{1}{2}$  feet of 8-inch pipe with dividing-plate; 30 feet of 5-inch diameter pipe; 8 feet of 4-inch pipe; two 5-inch junctions; two 5-inch knees; two 5-inch flanges; two 4-inch junctions; two 4-inch knees; four air-inlet brackets, 10 inches by 5 inches by 3 inches. When it is said that all the above will be made of strong galvanised iron, and will cost only four guineas complete, it will be plain that there is no charge for anything beyond the net cost of materials and workmanship. A plan and printed instructions are supplied along with each set of appliances. The system can be adapted to tenements at the same rates, every room in the largest block being ventilated separately. It can also be applied to existing buildings at a trifling extra expense. The Royal Commission on the Dwellings of the Poor, of which H.R.H. the Prince of Wales is so active a member, might with advantage give some attention to what Messrs. Boyle have devised, and which appears to be an effective and economical solution of a most difficult problem.

### THE IRISH ARCHÆOLOGICAL ASSOCIATION.

A MEETING of the Royal Historical and Archæological Association of Ireland was held in Armagh on the 6th inst., under the presidency of the Earl of Charlemont.

#### *An Irish Crannoge.*

Mr. W. F. Wakeman read a paper on a crannoge, or lake dwelling, which was lately discovered near Broughshane, and which is possessed of interest on account of the character of the objects found in it. They comprised—1. A sword-sheath in bronze,  $17\frac{1}{2}$  inches in length, richly decorated, and terminating in the figure of a snake-like monster's head. 2. One side of a second sheath slightly smaller than the former, covered with a profusion of so-called Celtic ornamentation, and exhibiting work in enamel of an extraordinary rare character. 3. An object composed of bronze, probably an amulet, the design and figure of which on either side constitutes a form of cross, which is not necessarily Christian. 4. An object in bronze, richly-decorated bands, in which are remains of white and red enamelled designs in a chevron or wavy pattern. 5. Three circlets of bronze, probably the rings of brooches or pins, one of which still retains enamel. 6. A small loop of bronze having the appearance of a finger-ring. Similar rings, however, have been found attached to pins. 7. A disc composed of thin bronze, ornamented upon one side with a graceful wavy pattern, the opposite face being plain. 8. Two objects in bronze, in form not unlike that of a modern door-handle. 9. Two pennannular rings of bronze, each measuring one inch and three-eighths in external diameter. They are perfectly plain and hollow. The metal of which they are formed is of extreme thinness, scarcely thicker than good note-paper. 10. A rivet-like piece of bronze. 11. A small stud of bronze, which may have belonged to one of the sheaths. 12. Portion of an armlet of jet. 13. A bead of opaque dark blue glass, relieved with streaks of white of the same material crossing each other obliquely.

The Rev. H. W. Leet presented some notes on remains in the county of Armagh. He was aware of the existence of four cairns, five kists, two crannoges, three pillar stones, two sepulchral mounds, seven raths, one stone fort, six churches, two hollowed stones, five crosses, one abbey, two bawns, eight castles, &c.

#### *An Irish Church.*

A paper by Mr. R. A. Young, architect, on the church of St. Columbkille at Knock, near Belfast, was also read. The author said that in Pagan times the site must have been a place of importance, as there are evidences of note still existing to justify this conclusion, notably a very large tumulus, or funeral mound, on which formerly stood a cromlech, the stones of which are now displaced, situated at a short distance from the site of the ancient church. The *Dublin Penny Journal*, in 1835, gave a woodcut of the ruined church as it then appeared, showing the two gables nearly perfect, one pierced by a square opening near its apex, the other with a traceried window. The author made his drawings and measurements in 1869, when the church was in a further state of dilapidation by the destruction of the western gable, of which only a fragment remained, and the mutilation of the eastern one, which had been deprived of the upper portion of walling. The interesting east window was, however, in much the same condition

as in 1835. Mr. J. H. Burgess, in 1872, made two sketches, which are probably the latest representations of the building, as soon after the eastern wall fell to the ground. The church has now completely disappeared owing to indifference on the part of those who should have taken an active interest in its preservation, although efforts were made by some local antiquarians to prevent this catastrophe. The space formerly occupied by its walls has been appropriated for grave lots, the foundations being removed for this purpose. The building measured 48 feet in length by 23 feet 6 inches in breadth externally. The walls were 3 feet in thickness, built of large field stones of the local silurian rock. The entrance doorway was probably in the western wall, which terminated in a gable with a square aperture below its apex, as shown to exist in 1835. The side walls were, no doubt, pierced by windows, but no trace of them remained. The most interesting feature was the eastern gable, which retained the upper portion of its original semicircular window, which had evidently been divided by a central mullion into two lights, with pointed heads and spandrel between, formed by their intersection. Relieving arches of rough stone were placed over the window internally and externally. The arch stones were grooved to receive lead lights, and holes had been cut at intervals for the insertion of Irish stanchions to secure them. A mason's mark, like a capital E, was incised on the under surface of one of the jamb stones. A window of the same design as regards the tracery exists in the little church of Logio, near Stirling, Scotland, as seen in the drawing made by the author some years ago. A square stone with a human head of life-size carved in high relief was inserted on the south side of the window, about six feet from the ground level. The carving was much defaced, but enough remained to show that a likeness had been intended of the shaved face of an ecclesiastic. The gravedigger employed in 1869 said that it represented the head of St. Columbkille. It is probable, from the position it was placed in, that the stone had been a relic of a much earlier church. The wall below the window was torn away in a suggestive manner. The western wall had been treated in a similar manner, as evidenced by the drawing in the *Dublin Penny Journal*. The sad fate that has overtaken in recent years this interesting old church adds another melancholy instance to the fate of Castlereagh. It may perhaps act as a warning of the danger of allowing ancient ecclesiastic and prehistoric structures to be left to the mercy of men who are in complete ignorance of the loss that the country sustains in the destruction of such monuments of its past history.

#### *Irish Metal Work.*

Mr. J. J. Phillips read a paper on a wrought-iron grille which still remains in the village of Richhill, near Armagh. Even the casual observer is struck with the dignity and breadth of treatment of the entire, and with the clever manner in which each field of vertical bars is alternated with panels of characteristic scroll work, the upper parts enriched with forgings, forming a sort of *chevaux de frise*, while the gates are crowned by convoluted and foliated forgings, which uphold the arms and crest of the owners, the details of which are manipulated with great taste and refinement. Sufficient effect is produced by simple treatments of the hammered bar without aping cut-stone mouldings or wooden carvings, or placing sheet-iron festoons and garlands in the humid atmosphere of the island, as is found so frequently done in the contemporaneous art iron work in England and the Continent; and where foliage is introduced here it is legitimate smith work, coming clean from the anvil, without filing, boldly forged out of the solid iron, and not flimsy *applique* of sheet iron work, which is the curse of modern art smith work for outdoor purposes. The vertical bars are 1 inch square, the gate horizontals  $2\frac{1}{2}$  inches by  $1\frac{1}{2}$  inches, the gate framings 2 inches square, the scroll work being 1 inch by  $\frac{3}{4}$  inch and  $\frac{7}{8}$  inch by  $\frac{1}{2}$  inch, tapering down. All through the work there is a moderation in the use of ornament other than constructional, and a sense of fitness for the purpose designed. The hammered bars and scrolls are not overlaid with sheet work, but depend upon the balance of arrangement in the straight bars and in the flowing curves. The main purpose of the structure as gates and railings is not lost sight of; and the vertical treatment is even emphasised by the decorative arrangement of the panels or grilles, which occur at intervals, and give rhythm to the composition as well as serving to frame in each field of verticals, and where, as cresting to the gate, the scroll work is allowed liberty and freedom in its rich and flowing lines in the spirals and the wrought-iron foliage, yet the entire has a playfulness in its conventionality, which shows the art power of the designer.

A **Mediæval Procession** will take place at Bruges at the close of August, and will be representative of incidents in the life of St. Charles the Good, the patron and former sovereign of the city. The dresses and appurtenances of the eleventh and twelfth centuries will be reproduced; and it is said that many of the highest ladies in Belgium will take part in the procession, and, wearing the costume of their ancestresses, will assume their parts as ladies in attendance on the court of their ancient count.

## NOTES AND COMMENTS.

It was characteristic of Mr. SHAW-LEFEVRE that he should not seek to force the scheme for the restoration of Westminster Hall on the House of Commons after hearing the speech of Mr. PEDDIE. The present First Commissioner of Works has endeavoured to carry out the duties of his office in the fairest way, and if the majority of archaeologists are found inimical to Mr. PEARSON's plans, we may assume that the proposed buildings will not be erected. It is, however, possible to go too far in succumbing to archaeology, which, in this case, has the advantage of being related to economy. The position of the proposed additions is in some respects the most important part of the group formed by the Hall and the Houses of Parliament; and by a liberal expenditure of money it could be made one of the most picturesque parts of Westminster.

THE first action taken by the representatives of the people who were killed by the fall of the chimney at the Newland Mills, Bradford, in December 1882, was tried in Leeds on Tuesday and Wednesday. The jury were unable to come to a decision on the points which were most essential. The owners of the mill went so far as to agree upon the damages which should be paid in case a verdict went against them, but the question was how far they were responsible for the negligence. The late Sir HENRY RIPLEY was one of those foolish men who think they know more about building than architects and builders. Apparently, as a matter of form, he employed architects to draw plans for his big chimney, but he altered the design, and had the work carried out according to his own whims. It was inevitable that the chimney must fall sooner or later, but are heirs who came into possession on the 9th of November to be made responsible for a catastrophe which occurred on the 28th of December, or a little over a month from the commencement of their ownership? A few days before the fall the agent called in Mr. ANDREWS, an architect, who thought that there was no immediate danger; but he asked if the engines could be stopped in order to make an examination of the interior. Engines cannot be stopped at a moment's notice, for it means suspension of work, and is therefore dependent on the orders which are in hand. The jury, however, seemed to be of opinion that the architect should have had the fires put out forthwith, although the mill was supplying power to several others. On this everything turned. If the architect was wrong and misled the agent, were the owners of the mill guilty of negligence? It is no wonder that, having created such a puzzle, the jury were unable to solve it, and both plaintiff and defendants can meanwhile claim the first trial as a victory.

THE exhibition which will be held at South Kensington in 1885 is to be of so comprehensive a character that it will be difficult to find space for all the objects which are to be shown. The title "Inventions and Musical Instruments" is not very happy, and suggests SHAKESPEARE and the Musical Glasses; but what's in a name? Irrespective of music, there are to be thirty-one classes, which are as follows:—Agriculture; mining and metallurgy; engineering construction, and architecture; prime movers and means of distributing their power; railway plant; common road carriages; naval architecture; aeronautics; manufacture of textile fabrics; machine tools and machinery; hydraulic machines; elements of machines; electricity; apparatus connected with applied chemistry and physics; gas and other illuminants; fuel, furnaces, &c.; food, cookery, and stimulants; clothing, jewellery, leather, india-rubber, and gutta-percha; furniture and accessories, fancy goods; pottery and glass; cutlery, ironmongery, &c.; firearms, &c.; paper, printing, &c.; clocks, watches, &c.; philosophical instruments; photography; educational apparatus; toys, sports, &c. These groups are so extensive it is difficult to see what is to be left for the year following to exhibit, unless objects which have been invented prior to 1862.

THE exhibits which come under the head of engineering construction and architecture will suggest the range of the proposed exhibition. *Roads*.—Methods and materials for constructing and paving roads, cleansing roads and pavements; road-sweeping machines, rollers, apparatus for the removal of mud, snow, &c., water-carts and other means of watering. *Railways and Tramways*.—Construction, excavators and

appliances used for earthwork and tunnelling, permanent way, rails, chairs, sleepers. *Bridges and Viaducts*.—Models, plans, and designs for arched, girder, suspension, trestle, and other bridges; apparatus used in construction. *Docks and Harbours*.—Models, plans, and designs for docks, harbours, piers, breakwaters, &c.; submarine construction, diving apparatus, dredging machines; pile-drivers, screw-piles, coffer-dams, graving docks, "patent" slips, caissons, pontoons, floating docks, hydraulic apparatus for working dock-gates, &c., gridirons, buoys. *Lighthouses*.—Methods of construction, appliances used in lighthouses and in lightships, fixed and flashing light apparatus, lamps, sound-signalling apparatus. *Rivers and Canals*.—Conservation and improvement of rivers; construction of canals; locks, lifts, and inclines; weirs. *Water Supply and Sewerage*.—Methods of collecting, pumping, storing, filtering, and distributing water; appliances for detecting and preventing waste of water; water-meters, water-fittings, filters; sewers, sewage disposal and utilisation. *Reclamation, Irrigation, and Drainage of Land*.—Drainage (natural and artificial) of low-lying districts, embanking and warping land, irrigation works. *Testing Apparatus*.—Apparatus and instruments used in testing iron, stone, brick, concrete, cement, &c. *Military Engineering and Fortification*.—Military topography. *Materials Used in Building*.—Bricks and tiles, machines for making them; concrete, artificial stone, cement, materials, and appliances used in their production; asphalt, roofing felt, and other roofing materials, columns, girders, and other applications of metal in building; applications of terra-cotta to buildings; preservative and fire-resisting materials, paints, &c., for application to stone, wood, iron, &c., methods of applying the same. *Building Construction*.—Models and plans showing methods of construction, non-combustible constructions; labour-saving and other machines and appliances used in building, scaffolds, elevators; fittings and appliances used in building, shutters, blinds, lifts, bells, speaking tubes, &c. *Heating, Ventilation, House Drainage, &c.*—Sanitary appliances, ventilators, cowls for chimneys, chimney-sweeping apparatus, apparatus for heating by steam, water, air, &c.; means of cooling air.

THE lighting of the Health Exhibition has been acknowledged by all visitors to be a great success. There is certainly as well as brilliancy, and the peculiar noises which so often accompany all systems of electric lighting are absent. The success is mainly owing to the perfection of the engines by which the electro-dynamo machines are driven. Six engines and eleven boilers have been designed and constructed by Messrs. DAVEY, PAXMAN & Co., of Colchester, for the purpose, and they have been running for several months without a single stoppage. The engines are fitted with the automatic expansion gear invented by Mr. PAXMAN, and to its use the great regularity of the lighting may be attributed. On no former occasion has so complete a collection of electric light plant been exhibited, and the shed in which the engines are found will well repay a visit from everyone who admires highly-finished machinery.

THE International Conference on Education at South Kensington will not be fruitless if the establishment of art museums in schools should be carried out, as recommended by the Head-Master of Rugby. A museum is found to be useful in several ways. It supplies the drawing-master with excellent examples, in both form and colour, the classical and historical teacher with the original of many a simile in the old poets; with the photograph of many a classical site, temple, or ruin; with the portrait, on coin or medallion, if not in life-size bust, of many an emperor, king, reigning favourite, general, or statesman; with the emblem of scores of cities in Italy, Greece, Asia Minor, and the Isles of the Ægean; with whole scenes from the civic or religious life of Greece, as in the reproduction of the Panathenaic Procession from the Elgin marbles; and to the student of the Middle Ages or the Renaissance of more obvious value still. Indirectly, an art museum is a great instrument for refining and elevating taste, and since an art museum was opened at Rugby a totally different and vastly better style of decoration has been adopted by the boys in their private rooms. The Rugby Museum was rather expensive. The buildings cost 9,000*l.*, the collections about 5,000*l.*; but in other places a less ambitious scale would serve. Boys as well as masters at Rugby contribute 10*s.* 6*d.* a year towards the expenses, and in this way about 200*l.* a year is obtained.

SEMI DETACHED HOUSES HAMSTEAD R.D. HANDSWORTH. JOHN P. OSBORNE A.R.I.B.A. ARCHITECT. 95 COLMORE ROW BIRMINGHAM.

VILLA AT COOMBE WARREN, SURREY.  
F. NESBITT KEMP, ARCHITECT.

JOHN P. JONES

## ILLUSTRATIONS.

## EASTERN CHESS PLAYERS.

**A**MONG the American artists who have settled in Paris and worthily uphold the reputation of the Western Continent, Mr. F. A. BRIDGMAN holds a prominent position. He has long since made his mark, and his pictures are among the most admired in the annual *salons*. Mr. BRIDGMAN was born in Alabama in 1847, and after studying in the art schools of Brooklyn and New York he became a pupil of M. GÉROME. From that artist he has acquired a love of Eastern life, which is almost unrivalled in the opportunities it presents for richness of colour, novelty of situation, and dramatic incident; but, happily, Mr. BRIDGMAN has remained unaffected by his master's cynicism when treating Eastern subjects. Whether in such everyday scenes as we illustrate, or in historic scenes like the *King's Sport*, exhibited at the Royal Academy a few years ago, and which represented an encounter between an Assyrian monarch and a lion, Mr. BRIDGMAN appears to be alike successful. In one respect his pictures are remarkable, and that is for the management of light and shade. An illustration in black and white has the drawback of failing to indicate colour, but it forms a test of chiaro-oscuro, and our plate will enable the public to understand one quality of Mr. BRIDGMAN's work. A painter who has already succeeded so well may be safely assumed to have a still more prosperous career before him, and America may be proud of so able a representative in art.

## STUART HOUSE, CADOGAN SQUARE.

**T**HE illustration of this house, which we publish to-day, is from a drawing exhibited in this year's Academy. It is a fine specimen of what can be done with good brickwork in thin courses with machine-made moulded strings partly rubbed. The effect of the double bay at angle is very pleasing internally, and we hope shortly to publish a detail of this feature of the building.

Messrs. HUNT & STEWARD and Mr. F. G. KNIGHT were the architects, and Mr. TITMAS, the builder.

## SEMI-DETACHED HOUSES, HANDSWORTH.

**T**HE houses shown in the illustration are situated on the Heathfield Estate, near Birmingham. The walls are of red brick, with stone dressings and Broseley tile roofs. Stourbridge glazed bricks have been used for the walls of bath-room and water-closets. The works have been carried out from the designs and under the superintendence of Mr. JOHN P. OSBORNE, A.R.I.B.A., 95 Colmore Row, Birmingham.

## VILLA AT COOMBE WARREN, SURREY.

**T**HIS illustration represents a private residence which has been erected on a portion of the Duke of CAMBRIDGE's Estate at Coombe, for Mr. W. T. PRITCHARD, from the designs of Mr. FREDK. NESBITT KEMP, architect, of 22 Chancery Lane, London. The contractor was Mr. J. J. GREENWOOD. The walls are in red brick, with black courses at the floor lines, ground floor bays in stone, the projecting windows of upper floors and gables being in timber framing, filled in with Portland cement, rough cast, and the roof covered with Broseley tiles. The premises contain four reception rooms, winter garden, greenhouse, gardener's dwelling, and stabling on ground floor, with the domestic offices in the basement, and eight bedrooms, dressing-room, bath, &c., over, besides good accommodation for coachman and gardener, with about two and a half acres of well laid out gardens. The house is particularly well situated, within a short distance of the railway station, Richmond Park, and Wimbledon Common, and commands very extensive and beautiful views.

## NATIONAL PORTRAIT GALLERY.

**T**HE twenty-seventh annual report of the trustees of the National Portrait Gallery has just been issued. The report states that the trustees have much satisfaction in including amongst their list of donations a copy in water-colours of Professor H. von Angeli's portrait of the Queen, by Lady Abercromby. The trustees also record with much pleasure the acquisition of five highly interesting legal portraits presented to them through the public spirit and liberality of the Principal and Antients of the Society of Barnard's Inn. The list of 286 donations, as given in their former

reports, June 9, 1883, may now be continued as follows:—Her Majesty Queen Victoria—a copy in water-colours, after the original portrait at Windsor Castle, taken in 1875 by Professor H. von Angeli; General James Wolfe, drawn by the Duke of Devonshire; Annie Jamieson, a bust by John Gibson, R.A.; Mary Somerville, drawn by J. R. Swinton. The following pictures, in accordance with a suggestion from the Chairman of the Board, Viscount Hardinge, also a trustee of the National Gallery, and with the full approbation of the trustees and director of the National Portrait Gallery, have been deposited in the National Portrait Gallery:—Sir David Brewster, LL.D., K.H., the philosopher, being the last picture painted by Sir J. W. Gordon; John Fawcett, the comedian, by Sir T. Lawrence; John Ha'l, the engraver, by Gilbert Smart; John Philip Kemble, as Hamlet, by Sir T. Lawrence—the portrait which has been often engraved; John Milton, by Pieter van der Plaas; Thomas Morton, the dramatist, by Sir M. A. Shee; the Right Hon. William Pitt, by Hoppner; Sarah Siddons, by Sir T. Lawrence; John Smith, the engraver, by Kneller; Wm. Smith, the comedian, by Hoppner; Sir John Soane, R.A., the architect, by J. Jackson; Catherine Stephens (afterwards Countess of Essex), the vocalist, by J. Jackson; Benjamin West, P.R.A., by Gilbert West; Right Hon. Wm. Windham, by Reynolds; Wm. Woollett, the engraver, by Gilbert Smart; King Edward III. and family, tracings from the original figures on the wall of St. Stephen's Chapel, Westminster; Edmond Malone, the Shakespearian commentator, by Reynolds; Joseph Hume, M.P., the politician, by Walton; General James Wolfe. The following pictures were presented June 11, 1884, by the Principal and Antients of Barnard's Inn:—Thomas, Lord Coventry; Sir Wm. Daniel Knight; Sir John Holt; Lord Chief Justice of the Queen's Bench, Sylvester Petyt; Wm. Cecil, Lord Burghley, K.G.; Benjamin Franklin; Admiral Sir Edward Codrington, G.C.B.; Captain Sir Thomas Bouchier, R.N., K.C.B.; Charles Fitzroy, second Duke of Grafton, K.G.; John Ker, third Duke of Roxburghe, K.G., K.T., a caricatura. In the previous report the purchases were stated to amount to 393. They may now be continued as follows:—Jonathan Richardson; Sir Henry Unton; Geo. Villiers, first Duke of Buckingham, K.G., and family; Sarah, Duchess of Marlborough; Joseph Addison; Thomas Cecil, first Earl of Exeter, K.G.; Sir Wm. Waller.

## THE ROYAL ARCHÆOLOGICAL INSTITUTE.

**T**HE annual meeting of the Royal Archæological Institute commenced at Newcastle-on-Tyne on the 5th inst. The members were welcomed to the city by the mayor, who, in his speech, briefly reviewed the history of the place. The President of the Institute (Earl Percy, M.P.) in replying said that thirty-two years had passed since they met in Newcastle, and it was gratifying to find a city which in the van of progress had not forgotten the claims of the past, or would not allow them to be crowded out by those of the present.

*The President's Address.*

The Duke of Northumberland then delivered the presidential address. His Grace maintained that there was no part of England which afforded so great and varied a field of interest for the archæologist as the Northumbrian district, and, in conclusion, said:—The daily life of the natives of the county was characterised by the rudeness and absence of culture and civilisation which a state of constant disturbance and danger naturally produces. He who is liable to have his house burnt over his head at intervals of five or six years is not likely to be very choice in his domestic arrangements. A most amusing description is given by an Italian who accompanied an envoy from Rome to the Court of the Scottish king, James II., in the fifteenth century. Lodged in a peel tower near the Tweed, he tells how the men came flocking into the fort, not deeming that anything worthy of notice would happen to wife or children, though they had to take refuge in the tower to secure their own lives; how they stood round the table as he dined, and passed from hand to hand bread given them as an article they had never before seen, and how the writer was astonished at finding the monks of the priory in which they were quartered on the Scotch side giving to the poor a dole of "black stones," to wit, coals. This state of things will sufficiently, I think, account for the comparative poverty of design and execution which generally characterises the ecclesiastical architecture, and which finds a counterpart in the stern and bare outlines of the military buildings. This is exemplified in the castles and towers with which this county is studded, where we have nothing to compare, I think, to some of the fortresses on the western frontier, or to Warwick, unless it be in the instance of Warkworth, which is a very curious and skilful attempt to combine domestic comfort and external beauty. Yet Prudhoe, Bamburgh, Dunstanborough, Norham, and Mitford are grand and striking examples of the feudal stronghold. When the feudal power declined, and more especially after the union of the crowns, many of these last were naturally abandoned, and fell to ruin, as the surveys made in the time of Henry VIII. and

Elizabeth show. Some, nevertheless, remain, additions having been made in subsequent reigns to fit them for more refined usages and habits of life than were aspired to by their first masters. Chipchase, Chillingham, and Belsay present most pleasing instances of this very picturesque combination. The remains of the ecclesiastical buildings are numerous and interesting; witness Hexham, Brinkburn, Holy Island, Tynemouth Priory, &c., and the details of their architecture will often be found very curious. But the rage of the destroyer has fallen heavily on most of them. The fine lines in "Marmion" describe well the results of the storm which swept over the Church of Rome in Henry VIII.'s days. Of all those I have named, and more that I have left unnoticed, Hexham only remains undestroyed. The rest present but ruined walls and desecrated shrines, save in the case of Brinkburn, lately restored to the proper condition of a place of worship by the munificence of its owner. You will be able to judge, if I may have the pleasure of seeing you at Alnwick, how complete the destruction there has been from the result of the excavations now proceeding; and, indeed, the reports of those who were entrusted with the survey of the buildings granted by the king to private individuals, are loud in their complaints of the injuries resulting to the Crown from the ruthless demolition of those edifices.

A vote of thanks to the Duke of Northumberland was proposed by Lord Aberdare, and seconded by the Bishop of Newcastle. Afterwards there was a reception by the local Society of Antiquaries, and the castle and cathedral were visited.

#### *The Provincial Spirit.*

In the evening the historical section was opened with an address by the Rev. Canon Creighton. Archæology, it was said, had done much for history in the past; it had gathered evidence of times when written records were silent; it had pieced together fragments of the life of the days of old, when the human voice was still inarticulate; and had settled disputed points, by appeals to the eye, on which there could be no doubt. In archæology, as in all other sciences, there were those who said that almost all had been done that could be done. Records of stones had been ransacked, explained, classified, and interpreted. Even if that were so, which was scarcely the case, there remained innumerable traces of the past still unrecognised and unsuspected. Local character, habits, institutions, modes of thought and observation—all were the result of a long process, differing in different parts of England. They were only to be seen and understood by a sympathetic searcher and observer, who looked upon each part of England in the light of its past; who saw that part, not only in ancient buildings here and there, but on the whole face of the land, and in the hearts and lives of its inhabitants. He admitted that this was no easy task; he admitted that the results of such inquiry must at first be very hypothetical and its conclusions tentative. But he thought that the inquiry was well worth pursuing, and it must be pursued speedily if at all. The present century had seen an enormous change pass over the whole of England. Local customs, local peculiarities, even local dialects were rapidly passing away. Men no longer live contentedly in the houses where their fathers lived before them. He said that English history had been provincial. It was rapidly ceasing to be so. Railways worked every year unnoticed transmigrations of people multitudinous beyond the host of Ida the Flame-Bearer. School inspectors demanded for the children throughout the land uniform knowledge, uniform ideas, and, as much as might be, uniform pronunciation. Our old provincial character was doomed to destruction. Unless its remnants were carefully gathered, the key would be lost to much that would be of growing interest to the antiquarian. Of this provincial history, no part of England possessed clearer traces than did Northumberland. It had always held the same position in English history from its very beginning. It had always been a border land. It was true that the border had varied in extent; but whether it were great or small, Northumberland had always been within it, and had generally formed its chiefest part.

The antiquarian section was opened by Dr. Bruce with a short address on the early state of Christianity in Northumbria.

#### *Alnwick Castle.*

On Wednesday the castles at Warkworth and Alnwick were visited. Both buildings were described by Mr. G. T. Clark. In the course of his address at Alnwick Mr. Clark said:—Probably this was the seat of a considerable Saxon estate, for at the Conquest it was certainly a place of some importance, and was speedily erected into a barony, and to it were attached sixty manors held by military service. The post was one of great danger, but to whom it was at first confided is uncertain. William was but once in Northumberland, when he visited Scotland in 1073, and carried fire and sword throughout the Border. Whether he was at Alnwick is unknown, but he must have crossed the Aln, and could not but have noted its capabilities as a line of defence. Duke Robert, his eldest son, paid an inglorious visit to the Border in 1080, and William Rufus was there both in 1091 and 1093. The Tysons are reputed to have held the barony during these visits, probably in some degree under the Mowbrays, whose possession of Bamburgh gave them great power upon the Border. The

earliest known Lord of Alnwick is, however, Yvo de Vesci, who was there towards the close of the eleventh century, and died before 1135. He certainly began the present castle, but Alnwick was already known by the death very near to it of Malcolm Canmore in 1035, who there closed his life and his fifth invasion of England. How the position was then defended is unknown. Probably, as was usual, the Norman lord contented himself with the Saxon defences, much like those in use in his own country, until he had time to replace them by works in masonry such as were then coming into general use. That this was so is rendered probable by the fact that the earliest existing masonry is late Norman, of about the year 1150. Had there been an earlier Norman keep it would not so soon have needed to be replaced, so that it may safely be concluded that the gateway now standing was part of the earliest castle in masonry; and further, from its dimensions and ornate character, and from the detached fragments of masonry of a similar date preserved in different parts of the *enceinte* wall, it may also be inferred that the new castle was on the present lines, executed in a handsome manner, and fitted to be a great frontier fortress and the residence of a wealthy and powerful baron. The rugged and dangerous life of a border baron of the twelfth century was very fatal to a long descent in the male line. De Vesci's heir was his daughter. She married Eustace Fitz John, who completed his father-in-law's works before his death, in 1157, leaving what is described as "a strongly fortified castle;" and no doubt his desire to complete it was quickened by its having been taken by David of Scotland in 1138, a few months before the defeat at Northallerton. The son and successor of Eustace adopted the family name of De Vesci, and in his time, in 1174, William the Lion of Scotland ventured too near to the castle, and was there taken by Ranulph de Clarville, the author of our first legal treatise, but also a great soldier. The new De Vescis came to an end in 1297. William, the last lord, left only a natural son, and constituted as his guardian the celebrated Antony Bec, Bishop of Durham, a warlike and not over-scrupulous prelate, who led the second line at Falkirk. Bec converted his wardship into a fee, and finally sold the castle in 1309 to Henry Percy. Percy was descended in the fourth degree from Jocelyn of Lovaine, of the House of Brabant, who married Agnes de Percy, and assumed her name, retaining his own arms. Sir Henry became Lord of Alnwick in 1309, and died in 1315. He seems at once to have taken the castle in hand. Castle building under Edward I. had undergone great improvements. The concentric, or Edwardian arrangement, had indeed been long anticipated at Alnwick, but flanking defences had come into use, and Percy recast the mural towers, giving them a stronger form and a bolder projection, and so arranging that each could be held, at any rate for a time, supposing the enemy to have entered the outer or middle ward. He seems to have introduced the portcullis, not always found in Norman gateways; to have constructed the gate-house, and to have built or rebuilt the great hall, kitchen, and other domestic buildings on a very handsome scale, though apparently within the lines of the old keep, which was probably a mere shell of masonry, with lodgings, as at York and formerly at Windsor, built within and against the walls. What the first Sir Henry commenced, his son, the second Sir Henry, completed. To him is due the inner gate-house, which, with the barbican and middle gate-house, completed the triple approach to the keep. No doubt there was always a wall dividing the two wards, but the Percys converted it into a spur-work, connected with the middle gate, so that even if an enemy breached the wall and obtained possession of the outer and middle wards, he would still be exposed to be harassed from the front and flank, as well as from the mural towers in his rear. The Percys continued to maintain the castle in good order, and the son of Hotspur obtained a license for walling the town in 1434. In those days the castle could accommodate a force of 3,000 men at arms, and forty hobelers, or light horsemen, and its lords were not men to maintain such a body in idleness. As was said of the Douglasses, they preferred "hearing the lark sing to the mouse squeak." All were men of action, of whom four fell in battle, one in a tumult, and three died in a state prison. Although not originally built by the Louvain Percies, it is remarkable how completely Alnwick has become identified with their name and fame. "The famous castle of a famous race." The salient points of their character, often opposed, are always striking. Headlong valour, military skill, great severity, and a courtesy not less great, a love of personal display, ample gifts for religious purposes, a great independence of priestly dictation, are qualities displayed continually by one or other of their line. Their figures, as we see them represented within the churches of their foundation, clad in complete armour, and surrounded by all the pomp of heraldry, but with sheathed swords and palms lifted up and compressed in prayer, present no imperfect illustration of their character. When the noblest and most popular of English ballads represents the Percy of his day as bending over his slain foe, and taking the dead man by the hand, it but expresses the strange and striking combination of savage warfare with the softest touch of humanity with which poets, rather than historians have painted the age of chivalry. The fame of the Lords of Alnwick was mainly earned upon the Scottish Border, and became a memory only when the two kingdoms became one. After the

accession of James the Northumbrian castles ceased to be of any military value, and the latter Percies resided chiefly upon their southern estates. One, however, the tenth earl, took an active part in public affairs, and sided with Essex and Manchester in the Parliamentary war. Neither the Percy heiress nor the Dukes of Somerset, her husband and her son, resided at Alnwick, and it is said that the first Duke of Northumberland found the castle in such a state that it was proposed to transfer the seat of the family to Warkworth. Happily for a later generation, this idea was laid aside, and between 1750 and 1780 the keep was restored in what was then considered to be the perfection of good taste, of which a very painful example may still be seen at Arundel. These restorations lasted till our time, until the accession of Duke Algonon in 1847. The Duke was a shrewd man of business, and possessed of great natural taste, much improved and expanded by foreign travel. After having well discharged his duties to his tenantry, to the Church to which he belonged, and to the county in which he held so large a stake, he set himself to work to restore the seat of his fathers to more than its ancient splendour. Happily he received the aid of Mr. Salvin, who, more than any architect of his day, understood how to restore, to rebuild, and even to add, without in any degree departing from the lines of taste and symmetry.

The parish church at Alnwick and Hulne Abbey were afterwards visited under the guidance of Mr. J. T. Micklethwaite.

#### *Church Restoration in Northumberland.*

The architectural section was opened by the Rev. Canon Raine, who said that in offering some preliminary remarks upon the great theme of architecture, he should endeavour to give a few descriptive hints and suggestions which wayfarers, such as they were, might find of some little use, as they inspected some of the chief objects of architectural interest which Northumberland could still exhibit. It was out of the domain of history that he looked upon the handiwork of ancient builders. The dates which the historian discovered were the framework upon which the whole system of architectural science was laid down. It was history, likewise, which reproduced men and manners, feats of arms and the achievements of the gentle life, without which stones were mere stones, and wood and water, the forest and the moor lost half their charm, and there was added to history in Northumberland the poetry of legend and tradition which invested tower and stream in this wide district with its own inimitable grace. Domestic architecture in Northumberland from the very earliest times was the architecture of defence, as was the case, although to a less extent, upon the borders of Wales. The Roman Wall, and the Roman fortified towns, which guarded or were strengthened by it, all told the same tale. From the earliest times to the beginning of the seventeenth century they had a record of local feuds and national strife, resulting frequently in bloodshed, and generating at all times hatred and alarm. Castles and towers stood in all parts of the county for defence, while under and around many of them the dwellings of the poor clustered for protection. Had religion no controlling power over the Borderers? Not much, he feared, when they were told that the thieves were good churchgoers, and that they were never more intent upon their devotions than on the eve of some great plundering fray or raid. Nor did the Reformation make any difference—at least, not for a considerable time. In Northumberland they found a composite style of architecture peculiar to itself. He must refer his hearers to the numerous specimens in the district of interlacing or basket-work, as it had been called, of a most interesting kind. In many localities there were few churches in the walls of which such carvings had not been found, and in a few churches there were remains of Saxon masonry as well. We had no Domesday Book in the North to show what churches were then in existence; but he thought that investigation, where documentary evidence failed us, would sooner or later show that wherever there was a parish church in the counties of Durham and Northumberland a century ago, there was a parish church on the same site in pre-Norman times. He might mention, with no small satisfaction, that there was every probability of these early sculptured remains being perpetuated by the graver's art at the cost of the University of Cambridge. That was a just tribute of respect to the country of Bede and Cuthbert. He trusted most heartily that before that meeting closed some message of gratitude and promise of help would go forth to Cambridge, possessing as that university already did a thousand claims to the sympathy and respect of the old kingdom of Northumbria. It was at Hexham that they would find the most interesting remains in the county of Anglo-Saxon work, and they might mark the influence of the place in the churches in the neighbourhood, beginning with Ovingham. At Holy Island and Farne—still more sacred ground—there was little of that date; there was next to nothing also at Tynemouth—later building had obliterated or concealed it; but at Whittingham, Edlingham, Bolam, Whalton, Longhoughton, and other churches they would find Saxon towers or masonry, whilst the interlacing sculpture met their eye in many of the churches and churchyards. He would ask them to contrast the condition in the last century with that of the present day. There had certainly been a most remarkable change. In the archdeaconry of Lindisfarne nearly every church had been either

built or restored within the last thirty years, not always wisely or well, but still assuredly not in the spirit of that Northumbrian vicar whom he could name, who chiselled away a whole corbel-table formed of grotesque heads, as he thought his congregation looked too much upon them when they ought to have been looking at him. In the archdeaconry of Northumberland there had been less done, but still a great deal. He was unwilling to criticise. He remembered an old friend of his making the caustic remark that mediæval architects erected buildings which we were unable to restore. He did not agree with that, but he did think that in far too many cases ancient remains had not been sufficiently respected, and that modern architects had often entirely overlooked the feeling and character of the architecture of the district in the work they carried out. Every county—nay, various parts of each county—had architectural features peculiar to themselves, with which an architect ought at least to make himself acquainted. There was an unhappy phrase in vogue describing the renovation of a church—"It has undergone restoration." It used to be—"It has been beautified." Now it is worse still—"It has undergone renovation." Poor church! He often thought what pangs it must have suffered! The stones must surely have been crying out. He was not one of those who would retain even discomfort and decay, and keep them empty rather than improve and preserve them. By all means they should make their church as fit as they could for the claims it had to meet, but they should value the past a little more than had been the custom. The most dangerous person of all was he who loved uniformity of style, and in his fabric would reduce all styles to one. That man sacrificed the historical story of his church to a very foolish caprice. Generally speaking, church vestries had far too much latitude and freedom of action allowed to them. Would they permit him, in conclusion, to make two or three practical suggestions? (1) Let every bishop have the advice of an architectural expert or experts before any structural changes were made in any church. The wanton mischief that had been done in the absence of such a rule as this was lamentably great. He could give many instances, and would mention two. Twice had he known the rebuilding of particular parts of churches urged and adopted on the plea that they were tumbling down. In each case, instead of tumbling down, they obstinately refused to fall or be moved. Were they allowed to stand, as they were perfectly able to do? No; in each case the architect vindicated the correctness of his ecclesiastical diagnosis by blowing the part up with gunpowder. (2) Whenever the fabric of a church was touched, let careful drawings and exact plans of the parts altered be first efficiently made and deposited in the diocesan registry. (3) Let greater attention be paid to monuments and inscriptions. They were being destroyed nowadays by hundreds and by thousands. He would simply remark that the legal value of these inscriptions was second only to that of a parish register; nay, in many instances they were far more useful, and that it was illegal to destroy them. To him it was most objectionable to see the monuments on a chancel floor sacrificed to an array of encaustic tiles, which in tone, colour, and comfort were infinitely inferior to the old grey or blue stones. Time was when such tiles were rarely seen out of a church; now one found them better laid and better cleaned in the passage of every second-rate hotel. Surely it made the church itself more solemn to see that under their feet were lying the dead of former generations. Were these memorials to follow in the wake of far too many memorials in this shifting age and perish with them? It was impossible, of course, to avoid the moving of such monuments occasionally, and if they spared them, time would not. He earnestly recommended that in all possible cases a full copy of the inscriptions in a church and churchyard should be taken by the minister, and that the copy should be deposited in the parish chest. If such a record were made decay was obviated, and removal was robbed of much of its mischief. He was glad to say that this suggestion of his had been already adopted in some cases, and he could not see why it could not be advantageously carried out in many more.

Mr. W. H. D. Longstaffe moved a vote of thanks to Canon Raine for his very interesting paper. With reference to the granting of faculties, he was of opinion that it was an illegal proceeding, and he should like to see the matter tested at law. The Church of England just now—he meant the archbishops and bishops—were going so entirely against the law of the land that some step should really be taken to stop their proceedings. He did not think that the clergymen should be punished, as they were so ignorant of church architecture. With regard to so-called restorations, which were not restorations at all, but were simply destructions, he entirely agreed with the remarks in that matter made by the president of the section.

Mr. Hodges seconded the motion. With regard to the rebuilding operations at St. Albans Abbey by Sir Edmund Beckett, a more wanton destruction of an English church had never been perpetrated. The destruction of the Abbey was now almost complete. He condemned the practice of removing the memorials of the dead from the interior of churches and replacing them with caustic tiles. He suggested that in order to aid in putting an end to this they should support the National Society for the Preservation of the Memorials of the Dead.

The motion was carried unanimously, and the meeting of the section terminated.

#### *Lindisfarne.*

On Thursday there was an excursion to Holy Island, when the Dean of Chester delivered an address on Lindisfarne Priory.

Mr. J. T. Micklethwaite said the ruins were an exceedingly interesting study, from which they could learn not a little, because they showed what a Benedictine church of the twelfth century was. All Benedictine churches were built in the eleventh and twelfth centuries. They were altered as people got more room or more ambition, till very often very little of the original work was left. Here it was not so. This work had not been free from alterations, but it retained its original character more than any other Benedictine church he knew. There was no tradition of an old cathedral there at all. It was an entirely fresh beginning in Norman times, irrespective of anything that might have been on the site before. The old church, part of the Scottish manor, might not have been such a shabby thing as some of their friends thought. It certainly was a wooden erection, but it was probably a fair size, because they could compare it with what they knew to have existed in other places. With that later building, however, they started entirely free from any previous structure. The apsidal end and other evidences seemed to indicate that the abbey was entirely Norman, and had been built at two periods.

Mr. Hodges differed from Mr. Micklethwaite in regard to the old Saxon church. He had carefully examined the ruins in company with eminent local antiquaries, and they came to the conclusion that the architectural history of the church had been written wrong all through. They believed it was all bosh about a wooden church; and that the site was the site of the Saxon church of Lindisfarne. He thought in the apsidal end they had the remains of a Saxon church. He should tell them that the church was built about 1130, after the nave of Durham Cathedral was finished, or was still going on; and it was almost a copy on a small scale of that cathedral.

Mr. Micklethwaite said Mr. Hodges's theory was a very tempting one, but he could not accept it without further testimony.

The parish church was inspected, and the rector exhibited some old registers and other records. There is a sketch in the vestry of the priory which was taken in the last century, when the building was in a less ruinous condition than it is at present.

#### *Bamburgh Castle.*

The visit on Friday was to Bamburgh, where was founded if not the first fortress in Britain the first Saxon work of which we know the date. Ida landed there and founded Bamburgh, and so completely were the Celtic inhabitants overwhelmed, that his name has descended to us as Ida the Flame-Bearer. Mr. Clark described what remains of the castle. He said they had come to see Bamburgh, and he hoped they would go away with a very pleasant impression of Bamburgh as being one of the grandest sights in the kingdom. As to the building, whether this or that particular piece of stone was of this date or that date, they could hardly tell. They had had a grand view, and must be content to go away with a grand impression. They had seen the interior of the keep, but it was not there they must study the interior of Norman keeps. That they must do at Newcastle. The exterior, however, had not been much meddled with, and it had some peculiarities. In the north they were to see, or had seen, some very fine specimens of Norman keeps. Newcastle keep, like that at Dover, was one of the most perfect specimens of late Norman keeps. At Bamburgh and Prudhoe they had rectangular Norman keeps. At Alnwick they had a very fine specimen of a shell keep; and at Durham next week, in viewing the grand combination of the cathedral and the castle, they would see another shell keep. They would thus have an opportunity, while in the north, of judging for themselves as to whether the rectangular or shell form of keep was the finer. Norman keeps were constructed for passive resistance, and one of the most successful modes of taking them was by undermining.

#### *Sculptured Stones.*

At the evening meeting in the antiquarian section, the Rev. G. F. Brown read a paper on "The Fragments of Sculptured Stones at Monkwearmouth and Jarrow," which was illustrated by a large number of rubbings. Mr. Brown pointed out the different features of the various sculptured stones at the two churches, and compared them with sculptured crosses and stones found in other parts of the country. The interlacing and scroll kind of ornamentation found in Wilfrid's work was, he pointed out, based on Roman ornamentation of a ruder character, and pointed to a time when there was a blending of the Roman and Celtic Churches. In support of this argument he showed rubbings from Roman remains now in the Black Gate Museum, belonging to the Newcastle Society of Antiquaries, and pointed out the resemblance between the style of ornamentation on them and on Wilfrid's work. He expressed his belief that many of the crosses found in ancient churches were older than the churches, and had stood at stations where the early Christian missionaries preached. He concluded by stating that the authorities of the University of Cambridge were considering the question of publishing autotypes

and historical descriptions of the ancient sculptured stones in the country, and hoped to obtain much assistance from local societies. The Newcastle Society were prepared to do the work in this district, and, if other societies would attend to their respective districts and co-operate with the university, he hoped the work would be done well.

The Rev. J. R. Boyle said he trusted there would be an expression of opinion in favour of the work which Mr. Brown had stated the University of Cambridge were engaged in. He felt sure that the members of the Newcastle Society would do their part both in work and expense. These sculptured remains were the earliest memorials of Christian art in the kingdom; they belonged to a time when Christianity was planted in these northern counties; and told us something of the spirit in which Wilfrid and those who worked with him laboured.

Mr. Evans said there was one element in this work to which particular attention should be drawn, and that was the Celtic element. The Roman and Teutonic influences were to be traced; but still more were the life and spirit of the ornamentation to be traced to the Celtic art, which was still existing in Britain at the time the Romans left the country. Some of the details of the ornamentation fit on to the details of the ornamentation found in the later Celtic work, and that work could be traced to a time before the Romans came to England. No finer specimens could be found than on the line of the Roman wall, in the castle here, and in the collections of Mr. Clayton and Mr. Blair. The great characteristic which separated the remains found in the north and west of Britain from those found in southern Britain was, that in the north there was a really living system of ornamentation; and that ornamentation was Celtic. It was owing to Celtic missionaries that Christianity first set foot here. It was thought by Mr. Brown that the crosses probably existed as centres of Christian worship before churches were built; and that might be supported by the view that the word church or kirk was said to be really derived from cross.

#### *St. Peter's, Monkwearmouth.*

The visit on Saturday was to the Saxon church of St. Peter at Monkwearmouth. The Rev. Mr. Boyle explained that the oldest parts of the structure were the lower part of the tower and the west wall of the nave. The edifice of which these were portions was the work of Benedict Biscop, who in 674 brought workmen over from France for its erection. The upper part of the tower belonged to the latter part of the eighth or the beginning of the ninth century. Mr. Boyle pointed out the evidences on which these conclusions were founded, and directed the attention of the party to some of the finer work of Biscop's workmen still in existence. The west wall of the nave was not bonded into the tower, and was probably built shortly before the tower. The chief features to be noticed in this wall were the two windows which undoubtedly represented the width and height of the original nave. They were interesting on account of the close resemblance to them of those at Jarrow, and also on account of the balluster shafts *in situ*. The delicacy of these balluster shafts was very marked in comparison with those of Jarrow. He had no doubt that the masons of Jarrow were Saxon, and that they copied, with less skill, the work of the French workmen at Monkwearmouth. The church had been renovated by Mr. Johnson, of Newcastle, and in the vestry were several balluster shafts and sculptured stones which Mr. Johnson found while carrying out the work.

The Rev. Mr. Brown remarked that the sculptured stones *in situ* in the tower were fast perishing on account of being exposed to the outer air, and unless something was done to save them they would have completely perished in our generation. He suggested that they should be carefully removed and placed in the vestry, beside the other collection.

Mr. Johnson said he was afraid that these stones could not be removed without endangering the whole tower. He would like to ask if it would not be possible to build a porch or screen round them so as to protect them from the atmosphere?

Mr. Micklethwaite said several old Saxon churches, with towers like that at Monkwearmouth, originally had a chamber to the westwards of the tower. Mr. Johnson told him that there were evidences of such a tower having existed in that case; and he would suggest that if such a chamber were erected again it would serve the purpose of protecting the stones they wished to preserve. Such a work in Mr. Johnson's hands they could depend would be excellently done.

Afterwards the church at Jarrow was visited. The chancel was said to be Saxon, and dated from about A.D. 681, while the tower and monastic buildings were Norman, probably between 1075 and 1083.

At the evening meeting a paper was read on the Saxon churches of Northumberland and Durham, by the Rev. J. R. Boyle.

On Monday the Chesters and the Roman wall were visited. Among the papers read at the evening meeting was one by Mr. R. P. Pullan on "The Discoveries at Lanuvium."

**The Island of Herm** has been sold by Messrs. Debenham, Tewson, Farmer & Bridgewater for about 7,500*l*.

## EXAMINATION QUESTIONS.

THE following are some of the latest examination questions relating to building which have been given by the Civil Service Commission to candidates for various departments:—

Give a vertical section, quarter full size, through both the wood and stone sill of a window-opening in a 14-inch brick wall. The stone sill to be 10 inches by 6 inches, resting on 9-inch brickwork. The wood sill to be 6 inches by 4 inches, the top being 2 feet 9 inches from floor line of room, with the bottom rail of a 2-inch double-hung sash resting on it. The section to be continued down to the floor line, showing a framed and panelled window-bank.

Draw, to a scale of  $1\frac{1}{2}$  inches to a foot, a cross-section of a 16-inch hollow brick wall, showing both glazed stoneware bonding bricks and galvanised iron bonding ties.

Draw, to a scale of  $1\frac{1}{2}$  inches to a foot, a section through three steps of a wooden stair, with 12-inch treads and 6-inch rise. Treads to be  $1\frac{1}{2}$  inches, with moulded nosings, and 1-inch risers, rebated and grooved to treads both edges; to be glued and blocked and supported by brackets nailed to a 6-inch by 3-inch rough string.

Draw, to a scale of  $\frac{3}{4}$  inch to a foot, the plan of a fireplace on an upper floor, with a 3-foot opening, 1 foot 6 inches deep. The main wall to be of stone 20 inches thick, and the chimney-breast of brick with a 14-inch by 9-inch flue running up on each side. Part of the floor round the hearth to be drawn, showing, on one side, 7-inch battens and a 4-inch oak margin, and on the other the naked joists, the common joists being 9 inches by 2 inches, and the trimmer and trimming joists 9 inches by 3 inches. Draw, to the same scale, a vertical section through the centre of the fireplace, showing a brick trimmer arch; also the ceiling carried on 3-inch by 2-inch ceiling joists. This plan and section to be coloured.

Draw, to a scale of an inch to a foot, the central cross-section of a wrought-iron box girder 60 feet by 5 feet by 19 inches; flanges to consist of four  $\frac{1}{2}$ -inch plates, webs of  $\frac{3}{8}$ -inch plates connected to flanges by  $3\frac{1}{2}$ -inch by  $3\frac{1}{2}$ -inch by  $\frac{1}{2}$ -inch angle irons; the rivets to be  $\frac{7}{8}$  inch.

Give a working drawing of a cast-iron pile shoe, with wrought-iron straps, for the foot of a whole timber guide pile.

Draw a part elevation of a stone pier for a bridge, showing irregular coursed or snecked rubble, the quoins to be rough punched with drafted margins.

A floor of 7-inch by  $1\frac{1}{2}$ -inch battens, secured to 3-inch by 2-inch fillets, is supported on Portland cement, concrete, and brick arches springing from the lower flanges of 12-inch by 6-inch rolled iron joists, placed 7 feet apart, these being carried by cast-iron columns 6 inches external diameter at neck. Give, to a scale of  $\frac{3}{4}$  inch to a foot, a cross-section through one bay, showing the construction of the floor, including the heads of the columns below. This drawing to be coloured.

In taking out the quantities of carpenter's work, what constitutes the difference between "fir fixed" and "fir framed and fixed"?

Taking an ordinary timber king-post roof, enumerate the different members under these two heads.

A wooden floor, 28 feet by 16 feet, consists of fir joists 10 inches by  $2\frac{1}{2}$  inches resting on ordinary wall-plates, two rows of herring-bone struts, and  $1\frac{1}{2}$ -inch battens ploughed and tongued. Take out the quantities for the same.

Explain how you would measure up the following:—Rubbed and gauged semicircular arches to door and window-heads. Chimney shafts and ornamental caps to ditto, in brickwork. Window sashes and frames. Slatting to roofs. Iron roof trusses. Down pipes and eaves gutters. Painting to doors, skirtings, and iron railings.

Give a section, to a scale of 2 feet to an inch, showing an 18-inch brick wall with a concrete foundation resting on stiff clay, 3 feet below the surface. The wall to be shown to a height of 2 feet above the ground level, and to be provided with a damp-course.

Specify the nature of the concrete and mortar you would use for the above work, there being good stone lime available.

What description of wooden roof truss would you use over a 25-foot span? Give a sketch elevation of the same.

Explain, by sketches or otherwise, the meaning of the following terms:—Flitch girder; rebated and filleted floor-boards; saddle-backed coping, throated; tile creasing.

What is the difference between a double floor and a framed floor? Give sketches of the same, showing the names of the different members.

Give sketches showing the ordinary section adopted for cast and rolled iron girders respectively.

What is a discharging arch? Show how it is applied in the case of a wood lintel over a door opening.

Describe the method of fixing lead flashings on the rake, against the end of a chimney shaft, in the case both of brick and of stone.

Show by sketches the difference between a ledged door and a framed and braced door.

Give a section through one side of an ordinary window-frame for 2-inch double-hung sashes, showing all the details.

Explain and illustrate the meaning of the following terms as applied to brickwork:—Batter, squint-coin, underpinning, brick-nogging.

Give the sizes of the different kinds of slates, and explain by sketch the meaning of laid to a 3-inch lap.

Explain the object of the damp-course, and state the different materials which are used for this purpose.

Give detail to a scale of 1 foot to 1 inch of 2-inch sashes and frames, double hung.

Draw to a scale of 4 feet to 1 inch a flat roof, covered with lead, size 20 feet by 16 feet, and give sectional detail of same to a scale of 1 foot to 1 inch, against wall, showing flashing, joists, &c.

Give plan to a scale of 4 feet to 1 inch of a timber floor, size 30 feet by 22 feet, showing trimming for staircase, 12 feet by 4 feet, in one corner, and give detail to a scale of 1 foot to 1 inch, showing girder, binders, floor and ceiling joists.

Draw to a scale of 4 feet to 1 inch a king-post roof, 26 feet span, and mark the names of the various timbers, and figure their scantlings.

The bottom flange of a cast-iron girder is 9 inches wide, depth of girder 12 inches, thickness of metal 1 inch, and length of bearing 18 feet. What is its breaking weight in tons in the middle?

Give the quantity of materials necessary for covering 90 yards, one coat work, with oil colour.

Explain the difference between pan and valve closets, and give sketch of a valve closet.

## BODIAM CASTLE, SUSSEX.\*

IN the year 1386 leave was granted to Sir Edward Dalyngrudge to erect and crenellate a castle at Bodiam. Thus is fixed for us the date of this building, just at the time of the introduction of that style of architecture which is called Perpendicular. It was built by a man then aged forty, who had passed his early manhood in France, under the leadership of those who in the great and glorious wars of Edward III., in which the superior discipline of the English had made them triumphant against great odds, had achieved the victories of Cressy and Poitiers. On his return he had married the heiress of the Wardedeux, and so became the Lord of Bodiam. He was one of the trustees of the kingdom during the minority of Richard II. We judge, therefore, that we are about to examine the work of a man who had large experience of affairs, both in France and England, then, indeed, at deadly feud, but which were, nevertheless, the leading nations of the world in all that regarded civilisation, art, and chivalry. The use of gunpowder had been introduced into war, but its ultimate consequences had not been fully foreseen; thick walls were still regarded as a safe protection, and their liability to fall on those who trusted in them under the fire of cannon was not yet realised. It was not as a mere exhibition of his power, and to gratify his taste as a soldier, that Sir Edward Dalyngrudge obtained leave to build himself a castle. Twice within a recent period had the town of Winchelsea suffered from the ravages of the French, and he who had carried war into France, and seen its effects there, may well have feared lest under the feeble rule of Richard II. England, and especially its southern coast, might in its turn suffer invasion.

On entering the courtyard of Bodiam, however, and picturing to one's self the two storeys of buildings now destroyed, but yet so easily to be traced as having been built against its almost perfect outer walls, one cannot help thinking how like after all this courtyard must have been to the interior of a mansion of no military pretensions, or even to the quad of a college. Here is no keep as at Lewes, Rochester, Arundel, Porchester, and a hundred others, where a garrison pressed to the last extremity could hold out for months, or even years, and wait for succour from without. Here are no tortuous ways along which an enemy who has attained one part of the fortifications must pass and expose himself to a flank attack before he reaches the next stage of the siege. The gates are strong, indeed, but were they forced the castle would be taken. We may, I think, therefore, consider that we have before us the work of a great soldier, anxious to secure himself from attack from foreign and domestic foes, and to add to his social and political importance, by building a castle in which he and, let us hope, his wife, the heiress of Bodiam, might live with considerable comfort and luxury. He selects a new site at a distance from the old mansion, and forms an ample moat, a moat so ample that one wonders whether its width had any special reference to the artillery range of the period. The site having no special features, the building takes a perfectly symmetrical form. The moat is crossed by drawbridges from the north, duly defended by a barbican capable of holding a small garrison. We may still see the place of its portcullis, and the winding stairs to the upper floor. Next is the main entrance between two towers. Over the

\* A paper by Mr. Lacy W. Ridge, read at the annual meeting of the Sussex Archaeological Society.

entrance are the arms of Bodiam, Dalyngrudge, and Wardedeux. Here are grooves for three portcullises, and we may yet see the outer one in its place, shod with iron spikes and lined with iron. In the vaulted roof of the gateway are holes for raining down on the assailant stones, melted lead, scalding water, or any other of those barbarous missiles used in war before the introduction of the "villanous saltpetre." At the top of the towers machicolations are provided for the same object as a means of defence against those who, with the aid of battering-rams or by mining, were engaged in an attack on the gates or walls. The large stone corbels carry a projecting parapet, and between them are holes through which the missiles were dropped. From the battlements like missiles and arrows were also poured on the assailants. Artillery, however, worked disadvantageously from so high a position, a dropping or plunging fire being manifestly far less destructive than that sent in a line parallel with the ground. Hence, in the lower storey of the towers we find embrasures for cannon, presenting externally a round aperture sufficient for the passage of the shot, with a thin slit above for sighting the gun. In the interior the embrasures are widely splayed to give room for working the gun. The curtain walls have battlements, but are without machicolations, their defence being provided for by the projecting towers. The towers at the angles are round, those in the centre of the sides are square; all were duly provided with battlements, but the southern or near tower only had machicolations.

The recognised mode of attack against such a building before the use of cannon became general would be to fill up parts of the moat, and gradually advance wooden towers against the walls, from which they could be advantageously attacked and ultimately scaled. Catapults would be used for throwing heavy stones against the walls, and archers would be watching their opportunity should any defender show himself above the battlements. Frequently mining would be resorted to, and the foundations of the walls being removed, they would be propped up with wood. This would be set fire to, the wall would fall, and a breach be effected. When, however, the attack on Bodiam actually occurred in the Wars of the Roses, it seems highly probable that the establishment of a battery of artillery on the earthwork on the rising ground to the north was sufficient to compel a surrender, for had a cannonade taken place we should hardly see so perfect a military ruin as it is our privilege to-day to visit. With the surrender of the castle in 1484 to the party of Richard III., just within a century of its erection, the use of Bodiam as a castle and a residence ceased. In the state of internal disorder in the kingdom, it became pretty evident that the fortified castles of the nobility were a source rather of internal danger than a means of defence against external foes. With the Wars of the Roses and the accession of Henry VII. castles in England became obsolete. In France they lingered longer, and in Scotland and on the border fortified houses had yet a century or more to prevail. In England the residences became almost purely domestic, and to the domestic side of the building before us we have now to turn. The very short time the castle was in use prevented any alterations from taking place, and that which remains to us may be regarded as wholly the work of the original founder.

Immediately opposite the main entrance is the door of the great hall, an apartment running the full height of the building, with the dais, bay window, and the only large window looking through the outer wall, and with a south aspect at its eastern or principal end. At the western end is the buttery screen, with the minstrels' gallery over, to which access seems to have been attained by a wooden stair. Next, with its door in the angle of the quad, is the kitchen, with two enormous fireplaces. The southern tower has a small portcullis, and this probably served as a postern or private entrance, reached, I should think, only by a boat, and so safe from sudden attack. Over the door are the arms of Sir Robt. Knolloyes, under whom Dalyngrudge served in Brittany. On the west side of the quad is an oven, and probably here followed laundries, stables, and other offices. An alteration, the only one in the building so far as I have seen, seems to have been made in connection with the two cross walls in this part. The east side of the quad was occupied by the private apartments of the knight and his lady. The south-east tower has a vaulted strong room. In the east tower there is said to be an oratory. The chapel, with its triple window, is easily distinguished. The altar step is visible, and there is a piscina. Adjoining the chapel is a sacristy with aumbrye, also a private gallery on the level of the first floor looking into the chapel. The north front probably furnished the apartments of the garrison. The towers were divided by floors into rooms, as the holes for the beams fully testify. Each room had its window and its fireplace, with back and hearth of hard well-burnt roofing tiles. The great attention paid at this time to sanitary matters may be seen by the constant recurrence on each floor of each tower of a well ventilated latrine, communicating by a shaft or flue with the running water of the moat. Neglect of sanitation was of later date. Turret stairs, finished with ornamental battlements, lead to the top of every tower. There we shall find the chimney heads, many of them still perfect. It is worthy of remark that there are no gargoyles, merely holes through which lead pipes would convey the rain water

from the roofs. I notice no corbels or other evidences of any intention to fix around the walls those wooden boards or scaffolds which Viollet-le-Duc tells us were frequently, though possibly only at earlier dates, in use during the times of a siege. Neither, although the lines of the lead flashings can be traced throughout along the top of the walls, can I as yet see the slightest evidence that the buildings here or the towers had those high-pitched roofs which give so striking a character to the restoration effected by Viollet-le-Duc under Napoleon III. of the contemporary Château of Pierrefonds. If, as seems probable—for there was certainly one small flat roof over the sacristy by the chapel—the roofs here were of low pitch and covered with lead, it shows how early the English abandoned the high roofs, which give such a picturesque effect to the châteaux on the Loire and throughout France, and to the castles and peel houses of Scotland, and in fact the domestic architecture generally of those countries as compared with the low and in later times apparently roofless architecture of England. I need not tell you that in the composition of this paper I have been largely indebted to the work of Mark Antony Lower and others who have studied here before me. My object has been to provide that we should, as far as may be, inspect this most interesting building with our minds attuned to understand that which is before us, and we may be glad that, through the instrumentality of those who have made such things their study, we are not now liable to fall into the error of an anonymous bard of the beginning of this century who, writing a poem of six cantos on Bodiam Castle, fixed the events he described some century before its foundations were laid.

## LEGAL.

High Court of Justice.—August 11.

(Before Mr. JUSTICE HAWKINS.)

NICHOLLS v. BAYNHAM.

RESERVES IN CONTRACTS.

This case, which was an interpleader issue, came on for further consideration upon the report of Mr. Harry Jones, the special referee. The claims arose out of a contract undertaken by Messrs. Braid & Co., in April 1881, to build a manor-house at Baldslow, in Sussex, for Mr. C. J. Ebdon. Messrs. Braid & Co. failed in July 1882, before the completion of the work. Under the contract, the architect, Mr. Norman Shaw, was bound to certify for not more than 80 per cent. of the work done, leaving a reserve of 20 per cent. in favour of the building owner. On this reserve a charge had been given by Messrs. Braid & Co. before their liquidation in favour of Mr. Nicholls, the plaintiff in the present issue, and the question was whether Mr. Nicholls was entitled to the benefit of his charge on the payments under the contract as against Mr. Baynham, the trustee of Messrs. Braid & Co., in liquidation. Mr. Baynham had, subsequently to the liquidation, completed the work at a considerable loss, the total expenses exceeding the contract price by some 3,000*l.* The contention of the plaintiff was that at the time of the failure there was a reserve due to Braid & Co. of 1,700*l.*; the defendant, on the other hand, contended that the architect's certificates were inaccurate, and that Braid & Co. had been paid for the whole amount of the work done up to the date of their failure. This was the question referred, and the referee reported shortly that 140*l.* was due to the plaintiff. Counsel for the plaintiff now argued that on the evidence given before the referee there was shown to be a reserve of 1,700*l.*, to which the plaintiff was entitled. The arguments on this point turned on somewhat complicated questions of account; but it was further contended on behalf of Mr. Baynham that, even if a reserve existed at the time of the failure, the trustee, having completed the contract at his own cost, was entitled in equity to all moneys payable under the contract, and also that the charge was given in fraudulent preference of other creditors and for an antecedent debt, instead of for advances for the purposes of the contract, as alleged by the plaintiff.

During the course of the arguments the learned judge made one or two suggestions with the view of promoting an arrangement, but without success until he was rising for the day, when a further conversation took place, which resulted in the matter being left in His Lordship's hands. His Lordship then said that he thought the plaintiff should receive 320*l.*, and a further sum of forty guineas, being half the costs of the referee, out of the fund in court.

Accordingly the case was settled on these terms.

Queen's Bench Division—Divisional Court.

(Before LORD COLERIDGE and Mr. JUSTICE FIELD.)

MEAKIN and MAY v. HARCOURT.

ARBITRATION AWARDS.

In this case the plaintiffs had been employed by the defendant to do repairs at the Clarendon Hotel, Anerley, now known as the Connaught Club, and certain disputes had arisen between them as to the value of such work and repairs, and with a view of settling

the dispute it was agreed that the work should be measured up, and the amount due upon such measurement should be ascertained by two surveyors to be nominated by the parties, and that the measuring-up should be referred to an arbitrator, who was to certify the amount to be paid for the work, the referees and the umpire to make the award within one month from the date. The arbitrators agreed to extend the time to May 9, and made the award on May 8, certifying the amount due to be 320*l.* after giving credit for sums due. The account not being paid an action was brought upon the award.

Counsel for the defendant moved to set aside the award, first, on the ground that the referee had not measured the work himself, but had it done by an experienced and skilled assistant, and, next, on the ground that the award was not made within the time limited, there being, he said, no power to the arbitrator to extend the time, and no such power in the Court under the Common Law Procedure Act or under the Judicature Acts.

The Court came to the conclusion that they had such power, at all events if there was an application to them to extend the time, on which plaintiffs' counsel made the application.

Defendant's counsel objected to an application without notice, and to the Court allowing the time to be enlarged for making the award.

Lord Coleridge said neither of the objections were good. As to the measuring, the measurement was to be ascertained by the referee, and it had been ascertained by him in the usual and accustomed way, and that was sufficient. Then as to the other point as to the time for making the award, the Courts had exercised the power of extending the time in analogous cases. Under the Common Law Procedure Act where no time was mentioned the time should be three months, and it had been held that the Court had power to enlarge that time, and so where there was an agreement between the parties as to an extension and the arbitrators had acted in excess of the power. These cases afforded obvious analogies, and the Court would follow them, and as it was obviously just to extend the time the Court would do so.

Mr. Justice Field said he quite concurred, and thought the case equally clear upon principles of law and justice. The question was one of measure and value, and it was not properly referred to skilled persons, and the measurement was to be done by a particular person as referee. The arbitrators being laymen and not learned in the law, thought they had power to extend the time, and agreed to do so, and the defendant, informed of it, did not object to it, and now, when sued upon the award, he objected to it, and took the objection, also, to the mode of measuring. As to the mode of measurement adopted it was obviously convenient. As to the objection to the extension of the time, it was clear that the Common Law Procedure Acts gave the power of extension.

The Court therefore upheld the award.

#### MARCH v. WINDUS.

##### CONTRACT FORMS.

This was an action on the contract contained in a receipt, dated Manchester, February 12 last, in these terms, written by the defendant and given to the plaintiff, for whom one Cahill was building a house:—"Received from Mr. March 30*l.*, under an agreement made with Cahill on account of the sums due to me in respect of the buildings at Worsley, and in consideration of such payment I undertake at once to proceed with the buildings." He did not do so to the satisfaction of the plaintiff March, who therefore sued him on the contract contained in that receipt. At the trial in the Salford Court it was objected that there was no valid contract with March, the plaintiff, who had contracted with Cahill, the builder. The judge, however, overruled the objection, and the plaintiff obtained a verdict.

The Court upheld the verdict on the grounds that there was a valid contract, but a rule *nisi* was granted on the ground of rejection of evidence.

#### WORKS IN PROGRESS.

**Messrs. John Hall & Sons**, of Bristol and High Street, Marylebone, W., have supplied the whole of the glass and completed the large dome at Madame Tussaud's new building in Marylebone Road. The building has been painted throughout with the special enamel paint supplied by the same firm.

**Hertford Corporation Town Waterworks.**—The "Abyssinian" tube well, for the entire supply of the town of Hertford, has been completed by the contractors, Messrs. Legrand & Sutcliffe, with most satisfactory results. The size of the tube well is 7½ inches; and at 81 feet the chalk springs are so abundant that the yield is over 100 gallons per minute, or about 150,000 gallons per day. The pumping, when necessary, can be continued night and day with a very small amount of attention, as the motor is a powerful water-wheel worked by the river Lea. The contrast between the clear and sparkling from the artesian spring and the turbid water of the river is very marked. This well affords a further illustration of the fact stated by Mr. Robert Sutcliffe at the recent water-supply conference held at the Health Exhibition,

that it frequently happens there is abundance of good water to be found on the banks of a river that is no longer itself fit to supply water for dietetic purposes. The total saving of the expense of filtration is also a very important item, which might, to some extent, recompense the London water companies for the expense of obtaining their supplies from sources that need no outlay on this head. The total cost of the tube well, including cast-iron connections to pump, was under 150*l.*; so that town supplies on this system cannot be considered extravagant.

**Wood Block Flooring.**—Mr. Lowe's system has been just adopted at the Cambridge Free Library; for the whole of the floors at the extension to the Midland Railway Hotel, Derby; the basement and first and second floors in connection with the Nicholson Free Library and Art Museum, Leek; floor of Turnstone Church, Vowchurch; carriage-house, Bradford, Yorks; floor of the Bon Marché, Liverpool; floor of Manchester and County Bank, Stalybridge; floors of lodges for Zoological Gardens, Liverpool; floor of joiner and carpenter's shop at Meltham Mills, near Huddersfield; floor of Chipping Campden Church, Gloucestershire; floors at St. Chrysostom's Church, Rusholme, near Manchester; floor of office for Messrs. Salmons & Sons, Reading; floor of fitting-shop for Messrs. Samuel Marsden & Son, Screw Bolt Works, London Road, Manchester; floor of billiard-room for Mr. J. Wardle, Leek, North Staffs.

#### NEW BUILDINGS.

**Ancoats.**—The foundation-stone of the parsonage which is to be built adjoining the church of St. James the Less, Little Newton Street, Ancoats, Manchester, has been laid. The parsonage is to be erected after the designs of Mr. H. C. Charlwood, architect, and is estimated to cost about 700*l.* The site, however, and the land adjoining, on which it is proposed to erect day and Sunday schools, have entailed an expenditure of 2,000*l.* It was explained that money had already been secured to defray the cost of the land and the expense of building the parsonage; but that the only sum in hand towards the cost of the erection of the schools was 26*l.* The cost of the parsonage-house would be 1,700*l.* altogether, but the site would cost 1,000*l.*, and the site for the schools another 1,000*l.*

**Hammersmith.**—St. John's Mission Hall, a view of which appeared in our issue of December 2, 1882, has just been completed. The building, which is a large and handsome one, of red brick with Bath stone dressings, has been erected from the designs of Mr. Hugh Roumieu Gough, who has adopted late fifteenth century Gothic of decidedly Flemish character for the work. The hall is 109 feet long by 30 feet 9 inches wide, with cloak-room, vestry, and retiring-room, and lobbies at the ends, with a large and well-elevated platform. In the basement accommodation is provided for a workman's club and institute, a kitchen for dinners to the poor and for other purposes, and ample provision for storage. The general contractor for the works, which have been executed at a cost of about 2,300*l.*, was Mr. John Lister, of Aston, near Rotherham, the mason's work being sub-let to Messrs. Tomes & Wimpey, of Hammersmith, and the carving of crockets, finials, and label terminations, &c., to M. B. de Szymanowicz, who has carried out his work with skill and taste. The building is warmed by means of Messrs. Musgrave & Co.'s slow-combustion air-warmers, placed in chambers below the floor-level. Mr. Geo. Linger, of Hammersmith, supplied the whole of the seating, tables, &c.

**Masonic Hall at Bo'ness.**—The foundation-stone was laid on the 8th inst. by the Earl of Mar and Kellie. The building will consist of two storeys. In the upper storey there will be a large hall, 45 feet by 30 feet, with a platform 27 feet by 18 feet, and having accommodation for 350 persons. The entrance to the hall will be from the south-west corner. Besides the hall, there will be on the upper flat committee and ladies' cloak-rooms. On the ground flat there will be a lesser hall, 30 feet by 18 feet, with ante-rooms, reading-room, games-room, billiard-room, lavatory, &c. The two last-mentioned rooms will be in the eastern wing of the building, while in the western there will be the keeper's house and public baths. The buildings are being constructed of white sandstone. Mr. Thomas Beattie, builder; Mr. Alex. McCallum, joiner; and Mr. Thomas Hodge, plumber, are the principal contractors. Mr. William Simpson, of Stirling and Bo'ness, is the architect.

#### CHURCH BUILDING AND RESTORATION.

**Astwood Bank.**—The new church of St. Matthias and St. George has been opened. The church is built from the designs of Mr. W. Jeffery Hopkins, of Worcester, and when completed will consist of chancel, nave, north and south aisles, porch, vestries, and tower. The style is that of the fourteenth century. The portions already erected are the chancel, the outer walls of the vestries, and the foundations and base of the tower. The spaces comprised within the walls of the chancel, the tower, and the vestries have been fitted up with temporary flooring and chairs, and will be used temporarily as a nave. This space accommodates over two

hundred persons. When the church is completed the centre part of this temporary arrangement will form the chancel and sanctuary, the north portion the vestries, and the south portion a part of the lower stage of the future tower. The temporary brick wall on the west side will be removed, and the arch which is already built, and may be seen from the inside, will be the chancel arch connecting the nave and chancel. The walls of the church are built of Bromsgrove stone, the inner walls being faced with brick, having ornamental band work. The contractor is Mr. Henry Surman, of Astwood Bank. The fabric when finished will cost 6,000*l.* or 7,000*l.* The part at present built will cost about 2,200*l.*

**Marylebone.**—The dedication-stone of a new chancel in the parish church has been laid by Mrs. Gladstone. To give space for the new chancel the present vestry will be removed, and from the rails in what is now the body of the church there will be formed a chancel of nearly 50 feet in length, including the depth of the semicircular apse, of which the diameter will be about 30 feet, that being the width between the walls of the wings. The interior will be decorated from designs by the architect, Mr. Thomas Harris. Walls and pilasters will be of richly-coloured marbles, and the bays will be enriched with mosaics and paintings on canvas fixed in the walls. Where the galleries are taken down, the spaces on either side between the windows will be decorated with paintings after designs by Mr. Armitage, R.A. The stained-glass windows will, on opposite sides, represent incidents recorded in the Old and New Testaments, types and antitypes. The subject of the reredos will be the Crucifixion, and in the four bays, two on each side, the lights will be filled in with representations of the Annunciation and the Transfiguration, Resurrection and Ascension. The mosaics will be the work of Messrs. Burke and Salviati. Mr. Conder is the builder. The cost of the new chancel is estimated at between 11,000*l.* and 12,000*l.*

**York.**—A new Wesleyan chapel, Clarence Street, York, was opened on Wednesday, the 13th. It is in the Italian style, and is built of pressed bricks from Messrs. Williamson's, near Hull, with stone dressings from Bradford; the columns of the portico are of polished grey granite. The interior is fitted up throughout in varnished pitch-pine; the ceiling is divided into panels and enriched with ornament; the organ recess has Corinthian pilasters and enriched entablature; a portion of the windows are of stained glass by Messrs. Winfield (late Camm Bros.), Birmingham. Accommodation is provided for 830 persons including free seats; there are also four large vestries or class-rooms. The total cost of the building, exclusive of boundary walls, has been about 3,000*l.* The contractors are:—Mr. Swallow for stone and brick work, Messrs. Bellerby for painting, Messrs. Walker for heating, all of York; the joiner's work has been executed by Mr. Deacon, of Shipley; the plasterer's work by Mr. Dixon, of Bradford; the plumber's work by Mr. G. Thompson, and the slater's work by Messrs. Pycok, both of Leeds; the gas-fittings and railings have been supplied by Messrs. Freeman & Collier, of Manchester; the ventilation by Hill & Hey, of Halifax; and the carving by Mr. R. Boys, of Leeds. The architect is Mr. W. J. Morley (now Morley & Woodhouse), of Bradford and Bolton.

### SCHOOL BUILDINGS.

**Kettering.**—Sunday-schools erected for Toller Chapel have been opened. The schools are built on the model of the American schools, and by arrangement of sliding shutters, the space surrounding the main building can either be shut off and converted into separate class-rooms, or the whole can be thrown into the large room. The total length of the large room is 60 feet, and the width 48 feet. It is covered with an open-timbered roof, stained and varnished, and when the class-rooms—which are lighted from windows in the external walls—are shut off, the central part of the room is lighted by clerestory windows and by a large ornamental window in the south-west end. The room is approached by means of two commodious staircases carried up in towers, the treads of the stairs being of Hayward's patent oak cubes, the remainder of the woodwork being pitch pine. Folding doors give access to the staircases, and these are arranged to open outwards for avoiding risk of danger in case of panic. The ground floor is occupied by a large infant schoolroom, in which is a gallery capable of seating 120 children. The floor of this room is of patent wood blocks laid solid. Beyond this is a corridor, from which branch off other corridors, leading to a series of other class-rooms of various sizes, the centre space also being available for small meetings. Mr. E. Barlow, of Rothwell, was the contractor. The sliding shutters were by Mr. Stone, of Ulverstone; the heating apparatus by Mr. Marriott, of Higham Ferrers; the cast-iron work by Messrs. Wright & Co., of Leicester; and the wrought-iron fencing and gates by Mr. Anderson, of Kettering; Mr. R. W. Johnson, of Melton Mowbray and Kettering, being the architect.

**Yeadon.**—School buildings for boys, girls, and infants have been opened. The building has been erected from the designs of Mr. W. J. Morley, architect (now Morley & Woodhouse, Bradford and Bolton). Accommodation has been provided for 1,070 children. The departments for the boys and girls are placed at either

end, while provision is made for the infants in the centre. The department for boys consists of two large rooms 53 feet and 75 feet long respectively, with a width of 20 feet in each, the height of the lock-couple ceiling being also 20 feet. That portion of the building devoted to the girls is similarly arranged, and each school has four large class-rooms opening out of the larger apartments. The total cost is a trifle under 5,000*l.*, and this sum includes the expenses for lighting and heating, and the boundary walls, which latter, on account of the nature of the site, has been an expensive item. Mr. Kenyon, of Yeadon, acted as clerk of works. The contractors were Messrs. Hargreaves, masons, Rawdon; Messrs. Taylor, joiners, Yeadon; Mr. Lumb, plumber, Yeadon; Mr. Edwards, painter, Rawdon; Messrs. Wheeler, plasterers, Calverley; and Mr. Stoner, slater, Bradford; while Messrs. Green & Co., of Leeds, have supplied the heating apparatus.

### GENERAL.

The Government have refused the offer of the Fountaine selection made by the syndicate, on the plea that the British Museum and the South Kensington Museum have ample funds for the purchase.

An Exhibition of Paintings, Decorative Art, &c., will be held in Eastbourne from September 4 to 13.

M. Ferdinand Gaillard, the French engraver, is now in London examining the various studies executed by Leonardo da Vinci for his painting of *The Last Supper*.

Mr. R. Winn, M.P., has contributed 580*l.* towards the restoration of the old Norman church of Thornton Curtis, Lincolnshire.

Mr. Ruskin will deliver a further course of professional lectures at Oxford in the October term. The lectures will, it is expected, resemble those which he gave seven years ago, in the last year of his first tenure of the Slade Professorship, and will consist of readings from his former works, with elucidatory notes and comments.

Mr. Darby, architect, has prepared plans for additional work-house accommodation at Cheltenham.

The Biological Institute of Great Britain have decided to erect their first Laboratory and Marine Museum on the Hoe at Plymouth, at a cost of 10,000*l.*

The Royal Archæological Institute will meet next year in Derby.

Messrs. Oldham, Chambers & Willins, architects, of Norwich, have dissolved partnership.

The London School Board have expended 139,023*l.* for the purchase of land for schools, and 136,803*l.* for the erection or alteration of buildings during the past year.

Mr. Charles Barry has proposed to the Metropolitan Board of Works, on behalf of the governors of Dulwich College, that a part of the College estate should be set aside as an open space for the public for ever.

The new Parish Church of Glendinnes, Banffshire, was on Monday struck by lightning and set on fire. The belfry was completely consumed, and the roof was much damaged before the flames could be extinguished. When its fastenings gave way the bell fell into the church, smashing many seats and some woodwork in the interior.

Blackfriars Bridge was on Monday partially closed for the purpose of being repaved. During the execution of the work three lines of traffic will be kept open, and will be regulated as usual by the police.

A General Inquiry is to be made into the drainage of the Lower Thames Valley. At present the inhabitants are liable to pay large penalties to the Conservators of the Thames.

Sir Henry A. Hunt has made his award in the case between the North-Eastern Railway Company and the owners of the Nail Works in Westgate Road, Newcastle. The premises are required for the railway, and a sum of 13,000*l.* was claimed for them. The award is 7,535*l.*

Count Saburoff, the late Russian Ambassador at the Court of Berlin, has sold his unique and valuable collections of classical antiquities. It is stated that the Eremitage of St. Petersburg has paid for the terra-cotta collection, 644,000 marks; the Berlin Museum, for forty-nine vases and sixty pieces of sculpture, 300,000 marks; and the British Museum, for the bronzes and other objects, 805,000 marks.

The Derby Town Council have received fifty-four sets of designs for their proposed new asylum. At the quarterly meeting of the council held last week, one of the councillors raised the question of the appointment of a professional referee, contending that if such a functionary were appointed the committee would have had plans from more experienced architects. He further alleged that the authorship of some of the designs was not a secret, a statement which several members of the committee denied; and as the subject dropped the mayor remarked that the Lunacy Commissioners would have to be satisfied upon any plan selected by the committee.

### COMPETITIONS OPEN.

**NORTH SHIELDS.**—Aug. 18.—Plans are required for Alterations and Additions to the Workhouse. Mr. Christopher Scott, Guardians' Hall, North Shields.

**STOCKPORT.**—Oct. 1.—Designs are invited for Public Baths. Premiums of £50, £30, and £20. Mr. Walter Hyde, Town Clerk, Stockport.

### CONTRACTS OPEN.

**BASFORD.**—Aug. 18.—For Additions to the Workhouse. Mr. H. Walker, Architect, Newcastle Chambers, Nottingham.

**BATLEY.**—Aug. 16.—For Building Dwelling-house. Mr. J. T. Law, Architect, 64 Commercial Street, Batley.

**BELFAST.**—Aug. 18.—For Building School-house to Baptist Church. Mr. William Hastings, 20 Victoria Street, Belfast.

**BELFAST.**—Aug. 19.—For Building Surgeons' Apartments at the Workhouse Infirmary. Messrs Young & Mackenzie, Architects, Donegall Square East, Belfast.

**BELFAST.**—Aug. 22.—For Building Aisles and Gallery to Drew Memorial Church. Mr. Wm. Batt, jun., Garfield Chambers, Royal Avenue, Belfast.

**BIRMINGHAM.**—Aug. 28.—For Erection of Kitchen and other Buildings at the Workhouse. Mr. W. H. Ward, Architect, Paradise Street, Birmingham.

**BOURNEMOUTH.**—Aug. 16.—For Building Sanitary Hospital at the Workhouse. Mr. G. R. Andrews, Surveyor, Town Hall Chambers, Bournemouth.

**BRIGHOUSE.**—Aug. 22.—For Building Warehouse. Messrs. G. Hepworth & Son, Architects, Brighouse.

**BRISTOL.**—Aug. 19.—For Rebuilding Avon Packet Tavern. Mr. H. Williams, Architect, 28 Clare Street, Bristol.

**CHEPSTOW.**—Aug. 20.—For Building Petty Sessional Court. The County Surveyor, 2 Bridge Street, Newport, Mon.

**COLCHESTER.**—Aug. 18.—For Building Villa. Mr. J. W. Start, Architect, Head Street, Colchester.

**CORK.**—Aug. 18.—For Building Twenty Houses. Mr. Robert Walker, Architect, 17 South Mall, Cork.

**CORNWALL.**—Sept. 2.—For Erection of Viaduct in Masonry at Guildford, Hayle, and at Redruth. The Engineer, Paddington Station.

**DAREMTH.**—Aug. 25.—For Enlargement of Gasworks at the Asylum for Imbeciles. Messrs. A. & C. Harston, Architects, 15 Leadenhall Street, E.C.

**DORKING.**—Aug. 18.—For Carrying-out System of Sewerage. Messrs. Smith & Austin, C.E., Hertford.

**DRIGHLINGTON.**—Aug. 16.—For Additions to Board Schools. Messrs. W. & R. Mawson, Architects, Exchange Buildings, Bradford.

**EAST COWES.**—Aug. 22.—For Construction of Sea Wall at Coast Guard Station. The Director of Works Department, Admiralty, 71 Spring Gardens, S.W.

**FLEETWOOD.**—For Building Business Premises. Mr. C. Pearson Shaw, Architect, 37 St. Peter's Place, Fleetwood.

**GRAYS THURLOCK.**—Aug. 19.—For Building Mistress's Residence and Additions to Board Schools. Mr. E. C. Allam, Architect, Romford.

**HAIFAX.**—Aug. 16.—For Rebuilding Excelsior Works. Messrs. Horsfall & Williams, Architects, Post Office Buildings, Halifax.

**HOLME CULTRAM.**—Aug. 21.—For Repairing the Abbey Church. Mr. John A. Cory, Architect, The Courts, Carlisle.

**LETTERKENNY.**—Sept. 1.—For Additions to District Lunatic Asylum. Mr. Morley, Building Surveyor, Commercial Buildings, Dublin.

**LLANISHIER.**—Aug. 22.—For Construction of Storage Reservoir, &c. Mr. J. A. B. Williams, Engineer, Queen's Chambers, Queen Street, Cardiff.

**LOCHMADDY.**—Aug. 30.—For Additions to Hotel. Messrs. Kinnear & Peddie, Architects, 3 St. Charlotte Street, Edinburgh.

**LONGTON.**—Aug. 20.—For Building Relief, Vaccination, and other Offices. Mr. E. Scrivener, Architect, Howard Place, Hanley.

**LOW SEATON.**—Aug. 23.—For Building Good Templars' Hall. Mr. G. D. Oliver, Architect, 44 Pow Street, Worthington.

**LUCTON.**—Aug. 19.—For Additions to Foundation School. Mr. F. R. Kempson, Architect, Hereford.

**MULLINGAR.**—Aug. 20.—For Building Post-Office. Office of Works, Dublin.

**NELSON.**—Aug. 26.—For Building Weaving Shed and Premises. Mr. Thomas Bell, Architect, 14 Grimshawe Street, Burnley.

**NETHERTON.**—Aug. 16.—For Foundations of All Saints' Church. Mr. C. J. Ferguson, Architect, 50 English Street, Carlisle, and 15 Dean's Yard, Westminster.

**NOTTINGHAM.**—For Building Public-house and Four Houses with Sale Shops, Hyson Green. Mr. Herbert Walker, Architect, Newcastle Chambers, Nottingham.

**OLDHAM.**—For Building Fireproof Mill. Mr. Joseph Stott, Architect, 26 Clegg Street, Oldham.

**OVERTON.**—Aug. 20.—For Building Police Court and Alterations to Police Station. Mr. T. M. Lockwood, Architect, 80 Foregate Street, Chester.

**PADIHAM.**—Aug. 20.—For Construction of Reservoir with Water Tower, &c. Messrs. Garlick & Sykes, C.E., 33 Winkley Square, Preston.

**PETERBOROUGH.**—Aug. 19.—For Building Dwelling-house, Westgate. Mr. James Ruddle, North Street, Peterborough.

**PRESTON.**—Aug. 20.—For Construction of Dock, Tidal Basin, Locks, Diversion of River, &c. Mr. E. Garlick, C.E., 33 Winkley Square, Preston.

**SKAITH.**—Aug. 25.—For Strengthening Roof and other Work at Wesleyan Chapel. Mr. W. Watson, Architect, Barstow Square, Wakefield.

**SUNDERLAND.**—Aug. 19.—For Building Six Cottages. Mr. W. Milburn, jun., Architect, Fawcett Street, Sunderland.

**TODMORDEN.**—Sept. 23.—For Construction of Reservoir, Ramsden Clough. Mr. James Farrar, C.E., Market Street, Bury.

**VAUXHALL.**—Aug. 20.—For Building a 40-quarter Brewery. Messrs. H. Stopes & Co., Architects, 24A Southwark Street, S.E.

**WALLINGFORD.**—Aug. 19.—For Building Water Tower, Cottage, &c. Mr. C. Hedges, Town Clerk, Wallingford.

**WALSALL.**—Aug. 23.—For Erection of Farm Buildings, Brockhurst Farm, for the Corporation. Mr. Samuel Wilkinson, Architect, Town Clerk, Bridge Street, Walsall.

**WILSDEN.**—Aug. 25.—For Building Mill, Shed, Offices, Engine and Boiler Houses, Chimney, &c. Mr. Wilson Bailey, Architect, 9 Market Street, Bradford.

AWARDED SEVEN PRIZES FOR SUPERIORITY, INCLUDING PARIS GRAND MEDAL, 1878, THE CERTIFICATE OF MERIT OF THE SANITARY INSTITUTION OF GREAT BRITAIN, AND THE AWARD OF MERIT AT THE INTERNATIONAL EXHIBITION, 1881.

TO ARCHITECTS.—THE BRICK of the FUTURE, that shall not get dingy or sooty like other Bricks, but, being of a Semi-Vitreous nature, will maintain a clean and washable surface.

## FACING BRICKS AND BRICK ORNAMENT OF TRUE TERRA-COTTA, AS ALSO ARCHITECTURAL WORK, IN WHITE AND WARM-TINTED BUFF.

Made from the Finest Terra-cotta and Stoneware Clays, of a warm and pleasing appearance, of beautiful and superior quality and finish, non-absorbent, acid, fire, and alkali proof, will resist the most severe frosts, and when tested were found to withstand a pressure of 445 tons to the square foot. They have been used in the most exposed parts on the North and South Coasts, and being true Terra-cotta, are warranted imperishable.

Pattern Sheets and Price Lists of superior Glazed Stoneware Sanitary Pipes, and Fire Clay Goods, Chimney Tops, &c., on application.

Sole Manufacturers:—CANDY & CO., Limited, GREAT WESTERN POTTERIES, NEWTON ABBOT, AND 11 QUEEN VICTORIA STREET, LONDON, E.C. Who are also Sole Makers of the celebrated "Granite Vitified" Paving Bricks for Yards, Stables, and Footpaths, and "Granite Vitified" Damp-proof Building Bricks. as used by H.M. Government for dock construction, &c. Samples free to Architects and Engineers.

WIMBLEDON.—Aug. 26.—For Building Press House, Cake Shed, and Plant for Treatment of Sewage Sludge. Mr. W. H. Whitfield, Local Board Officer, Broadway, Wimbledon.

WINSFORD.—For Building Chapel. Mr. Herbert Isitt, Architect, Queen Anne Chambers, Bradford.

YORK.—Aug. 18.—For Restoration of St. Crux Church. Messrs. Fisher & Hepper, Architects, 16 Castlegate, York.

## GRUNDY'S PATENT WARM-AIR VENTILATING FIRE GRATE.

The novelty, superiority, and advantage of this patent consist in the heating surface being greater than any other Fire-grate introduced to the public. It is very simple in construction, and is made in the form of a Stove, the back of which is semicircular in shape, with gills behind and smoke-nozzle on top, all cast in one piece. The same can be attached to any design of a Register or Stove front. It is very suitable for schools, class-rooms, waiting-rooms, hospitals, offices, dormitories, and dwelling-houses, from the cottage to the mansion. Design and specification post free on application.

## TESTIMONIALS.

"9 Victoria Chambers, Westminster, S.W.  
June 10, 1884.

"SIR,—I have much pleasure in testifying to the efficiency of your patent Warm-Air Fire Grate. It has been very successful, and given every satisfaction where I have used it.

"Yours, &c.

"JAMES WEIR, F.R.I.B.A.

"To Mr. Grundy."

"Baptist Chapel, Clapham Common, London. Richard Webb, Pastor, 10 Grafton Square.

"February 15, 1884.

"DEAR MR. GRUNDY,—I have pleasure in testifying to the excellency and efficiency of your patent Fire-Grate. It is the most charming invention for heating a large room I have ever known. I shall have pleasure in showing it to anyone who wish to have their schools or rooms pleasantly and efficiently heated."

From James Garry, Esq., Architect, West Hartlepool,  
July 1884.

"DEAR SIR,—I have very great pleasure in stating that the first stove, or patent warm-air ventilating fire grate, adopted by me in school at Seaton, and a second in a Cocoa Palace, have given such satisfaction that I now order eleven to be inserted in New Upper Grade Schools in course of erection at West Hartlepool. They are the most economical, efficient, and easily managed stove at present before the public.

"Mr. John Grundy."

Apply to JOHN GRUNDY, 30 Duncan Terrace, City  
Road, London.  
Works—TYLDESLEY, near MANCHESTER.

# The Architect.

## THE COMING RENAISSANCE.

QUESTION which cannot fail to be exercising the minds of a good many enterprising architects just now is one which some others may think to be very easily answered, although it is not—what is Renaissance architecture? It is coming into fashion, or has come in; its demands must be met; the first in the field will have the advantage in its revival; business is business in this as in everything else; it is necessary, therefore, to understand exactly what it is.

The facility—we may almost say felicity—with which English architects of the present day are able to accommodate their hand to a new fashion is a remarkable incident amongst the conditions of artistic practice. The operations which have recently taken place in Queen Anne design—if we may use this commercial phrase to indicate the somewhat peculiar character which the transaction appears to take—have been most creditable to the versatility of English genius. Whatever may be said on the question of artistic stability or loyalty—perhaps it may be called conscience—there can be no doubt that the readiness with which leading men of the business-getting order have played the weather-cock (as hypercriticism may call it) has been phenomenal. But yesterday Gothic was their only wear. To-day it is Queen Anne, and poor Gothic is put away. To-morrow, what is it to be?

Now we are speaking quite seriously when we take credit to English architectural practice for this, and when we repeat once more what we have frequently taken occasion in this journal to say—that it is idle to sneer or even to smile at the present phase of artistic development more than any other. They who are philosophical enough to entertain high hopes of the future of the art in England will see in the present condition of things only another warrant for their expectations. The wider the field which they include in their survey, the more encouragement may they find; but even in the narrowest view of the current architectural mode—as an odd old fashion merely which has been introduced by accidental sketchers of Flemish picturesque for the amusement of a somewhat *blasé* Gothic fancy—the cleverness with which the lesson has been learnt, and, as it were, translated into modern English, is most remarkable. The Gothic schoolmen of thirty years ago were not by any means so successful, even although the unprecedented enthusiasm which took possession of them added enormously to their confidence and vigour. Perhaps the Gothic style which they produced (we are leaving church work, of course, wholly out of account) was less tractable; indeed, we may now say that it was in every way most difficult to deal with—a thoroughly hard-mouthed style. But even in Gothic work (of the municipal or civil order) it cannot be denied by anyone that English designers frequently did themselves the greatest credit, and it may very likely be suggested by many shrewd observers that when in the Queen Anne style the same men and their pupils are now working with such great freedom and effect, it may not be, after all, because they have more easy materials to handle, but rather because they have by former exercise acquired a special dexterity in handling whatever may come: which dexterity, we take leave to add, is the quality whereby, if we are right in our impressions of the case, the next phase of English architectural art is to be particularly benefited.

In other words, the faculty of utilising an antiquated artistic mode by taking it in a spirit of its own and adapting it to modern purposes, without any very material compromise of its idiosyncrasy, seems to be peculiarly an English faculty. The work which is done on this principle may be called copying if the term be insisted upon; but it has now become copying with a peculiar merit which involves so much in the way of original artistic adaptation that it is a different kind of copying altogether from that literal simulation which produced the best examples of the neo-Greek of Munich or the Palladian Italian of Europe at large, to say nothing of the modern Gothic of the High Church in England.

The way in which our brilliant neighbours in France exercise the faculty of imitating antiquated or exotic styles of art is well known; and it is entirely different from this English practice. A trained Frenchman will accept with the most perfect equanimity any mode one chooses to dictate to him, from ancient Egyptian to modern Chinese, or Russian to Irish, and, promptly translating it into the language of the Palais Royal, will express himself with the utmost confidence and courage, producing the most clever things in the world (in their way) with a finesse of which it is needless to say another word. But, however smart and pretty all this artistic fluency may be, and however truly meritorious in these respects, it is plain that the term imitation must be applied to it in quite another sense from that in which we use the phrase with reference to English work; and when, on the other hand, we see such a man as VIOLETT LE DUC, in full panoply of archæological lore, professing to reproduce Mediævalism with an authenticity that is not allowed to be questioned, the result is as hard and mathematical as, like the original, it ought to be fanciful and unrestrained. The fact that nicety may be altogether too nice is here palpably proved; and, at any rate, whatever advantage French art may otherwise derive from this daintiness in such work as emanates from the genuine impulse of the moment, the peculiar merit of being able to enter fully into the spirit of historical character we may claim, let us say plainly, for England alone.

In this view of the matter, then, what course are English architects to pursue in the revival (for we must so call it) of Italian art, which is now supposed to be imminent? We speak here of revival advisedly, as if it were the only process by which the eventuality of a change of architectural fashion in these days is to be accomplished; and the foregoing reflections sufficiently explain the reason why, if only as regards England. Our present Queen Anne work no one imagines to be anything like a permanent style. If everything in this world is in transition at the best, *a fortiori* is such a mode as this a transitory manifestation, leading to some more academical act of development beyond; and it appears to be now pretty generally accepted that the only legitimate outcome of the transition must be "Renaissance." What, then, is this Renaissance to be?

A few years ago, when the change in prospect was beginning to be talked about, it was quite a characteristic circumstance that speculation should turn upon the idea that it would be a matter of choice for leaders of change to determine what "period" of Renaissance ought to be experimented upon for their selection, and Gothic doctrinaires were prompt enough in proclaiming that "early" Italian alone was admissible. This obviously meant no more than that the current revival of the authenticities of Gothic art should be carried forward on new ground to another century, taking care, however, that the reform should stop short of the point of actual revolution. The term "Renaissance" was therefore made to include the transitional twilight which in Italy preceded the eventual birth of day; and no doubt this was perfectly allowable in the language of revivalism. But the mistake still remained which is always involved in the notion that even revival can be made a question of individual choice out of the books; a mistake which is proved by any number of clever examples, from HORACE WALPOLE'S villa and the Brighton Pavilion to PRINCE NAPOLEON'S Pompeian house and the Natural History Museum at South Kensington. So also at the present moment, granting to the utmost all that attaches to the principle which seems to constitute Englishmen the great masters of revival in its best form, we do not think the coming revival of a Renaissance style in England is to be directed or even controlled by the force of will of any individual leader of the profession. Holding, for instance, as we do, that even such a minor manifestation as the Queen Anne fashion is not to be identified with personal leadership, but only with a general movement of public opinion, much more must we look forward in respect of the more academical outcome of it for which every one is waiting, to some manifestation, probably of leisurely growth, which shall involve a development of the universal taste of the country. Perhaps the nearest approach to a direct act of personal artistic influence in the architecture of modern England is to be seen in BARRY'S club-houses; but we can only observe at present that this may after all be quoted, perhaps, as an exception which proves the rule.

It is most likely, therefore, that the Renaissance whose introduction is now in progress in England will not turn out to

be any pure reproduction of the historical style of the Italians. Perhaps we may presently see the mode of some individual master or some particular school working its way to the front; indeed this form of development is probably the only course to which precedent points; but if we are right in our estimate of the *forte* of English architects, the authenticity of it will be only accepted in principle in order to be translated into a language of their own. Absolute originality is out of the question; literal copyism is not to be apprehended; the motive examples of the coming style are not yet to be guessed at; they and their representative man will appear together.

## ANTIUM.

[BY A CORRESPONDENT.]

WITH the thermometer registering upwards of 90 degs. Fahrenheit in the shade—it has reached 97 degs.—it is no wonder that the Romans should betake themselves to their various bathing establishments and seaside resorts. Of the latter, there is not a great choice within easy reach of Rome. Palo, Civita Vecchia, and Porto d'Anzio are the principal, indeed almost the only seaside places eligible for a day's run and a dip into the sea. Neither of the former are great favourites, but the last-mentioned is quickly establishing itself in popular estimation, and certainly deserves the distinction.

Those who visited Porto d'Anzio fifteen or twenty years ago will remember it as no more than a remote seaside hamlet, chiefly built on the quay, a resort of Neapolitan fishermen and of quail-shooters in the season of that migratory bird. From this little port a sweep of sand and a sparsely frequented road led to the nearest town, Nettuno, two miles distant. Almost the only house between the two places was the country villa of the BORGHESI, which rose above the wooded upland that skirted the bay. The spot was at that time so desolate, so little connected with the outward world, so breathing of the departed grandeur of a vanished civilisation, that it appeared to be pervaded with a spirit of intense melancholy; and even now in the winter time, when the sky is clouded over and the shore is beaten with "the melancholy wash of endless waves," it seems as if it was not able to shake off traces of the old mourning, of the centuries of oblivion and gloom, which have so long enshrouded it.

But now it is suffering a change. Direct railway communication with Rome has brought its thirty-six miles' distance within an easy journey, instead of the discomfort of the lumbering diligence and circuitous route by which it was formerly reached. Bathing establishments—the slight variations of tide in the Mediterranean rendering the movable caravan unnecessary—grow by the waterside. Villas rise on every hand, hotels, and lodging-houses. Porto d'Anzio, undoubtedly, will soon be the Brighton of Rome. The young lady can here show the "last thing" in figured skirts, and the "masher" exercise his fascinations. It must, however, be fairly confessed, to the credit of the Italian people, that fashionable follies and affectations are less prevalent with them than with us.

Porto d'Anzio, it will be remembered, is the ancient Antium. It lies almost as far to the south of the mouth of the Tiber as Civita Vecchia does to the north of it. It was one of the most ancient cities of Latium, and subsequently became the capital of the Volscian territory. It was taken by the Romans in the fourth century B.C., and thenceforward became a part of the Roman dominions, and one of the most important Roman seaports. The historical circumstances connected with the place are many and interesting. It is associated with the revolt of CORIOLANUS. It was the birthplace of the emperors CALIGULA and NERO, by the latter of whom it was in a great measure rebuilt and beautified. It was the favourite resort of many emperors. AUGUSTUS was here first styled the father of his country—*Pater Patriæ*. CICERO had a villa here, to which he often alludes in his writings. It was the seat of a famous and splendid temple of FORTUNE, the deity whom HORACE addresses in one of his most beautiful odes as presiding over the city:—

O Diva gratum quæ regis Antium.

It had also a celebrated temple of ÆSCULAPIUS: for when, according to the old legend, the god was being brought from Epidaurus to Rome in the shape of a serpent, he here left the vessel to pay a visit to the shrine of his parent, APOLLO. NERO

brought hither a colony of veterans of the Prætorian Guard. He constructed a fine harbour consisting of two moles enclosing a basin about two miles in circumference. The marble of his palaces shone from the headland, and many noble buildings gave importance to the city. Here were found many celebrated marbles, amongst others the *Apollo Belvedere* of the Vatican, and the *Fighting Gladiator* in Naples.

But Antium, like Rome itself, only grew to decrease. The port appears to have retained a degree of importance up to the sixth century, after which it rapidly declined, a decline which had been inaugurated by the establishment of the Byzantine empire. In the eighth century the irruption of the Goths, Longobards, and Saracens completed its ruin. In spite of the attempts since made from time to time to resuscitate some portion of its former splendour, it has been gradually abandoned to the winds and rains of heaven.

But although there is so little of it left, that little to the thoughtful mind, over which an eventful past always exercises a fascination, is well worth exploring. Ruins of the old Latian city still exist in fragments of huge stonework occasionally discernible on the rising ground about the shore, but more of the more recent Roman city are seen in the extensive substructures that flank the sea-shore a little north of the modern town. First of all the fragments of the moles strike the eye here and there, rising from the sea in almost the whole extent of their lines. They were laid upon piers, substantially built of concrete, thus forming arches by which the tide could flow in and out. The whole line of coast is here honeycombed with chambers and recesses, built of concrete *lateritium* and *reticulatum*. What precise purpose these chambers may have served it is impossible to say. In one place an extensive façade of varied structure faces the sea. Emerging from the masonry both on the shore and above it, stout beams or posts appear, which seem even to have survived the more hardy material in some places. They have been built into the solid masonry, and there is nothing left to show that they supported floors or roofs. They are found throughout the whole extent of the ruins, sometimes isolated, sometimes in groups or rows. They are very puzzling as at present seen. The pebbles of the shore, with which indeed it is thickly strewn, are almost entirely composed of fragments of marble and mosaics, materials not native to the district, showing how great must have been the grandeur and magnificence of the vanished city.

Antium has been very imperfectly excavated. There is little doubt that further research would lead to important discoveries, as substructures of buildings are found extending a considerable part of the distance between Porto d'Anzio and Nettuno. A visit to the latter place is interesting, of which some account may be given. It is larger and more compact than the modern Porto d'Anzio, and is almost purely Mediæval in its aspect. It sits, as it were, on the very front of the waves, thus justifying its name, Nettuno (Neptune), a name supposed to have been bestowed upon it from a temple of that god which once stood there. Its early history is not known, but it probably formed a part or suburb of the larger Antium. In the eighth and ninth centuries, the whole district was overrun by Saracenic pirates, who devastated the coast, and, it is supposed, formed a settlement here, traces of which still remain in the physique and character of the inhabitants. It was in the Middle Ages taken possession of by the ORSINI, and was subsequently held by the COLONNA. In the sixteenth century it was sold to the Church with feudal rights and vassals, "as if," as a local chronicler adds, "they had been herds of cattle." Indeed, one cannot help dwelling for a moment on the condition of these vassals or tenants of those times, who appear only to have been allowed to live simply and solely to furnish plunder to their oppressors. They were not able, excepting under severe penalties, to sell or buy, or even to eat and drink under any other circumstances than those prescribed by their feudal proprietors. They had to fight their battles and furnish their houses. It mattered little to them who gained the continually-recurring contests. They were sure to suffer in their persons, their property, and their families. Even yet traces remain in Italy of this state of things, which was retained when it had died out from most other parts of Europe, in the indifference of the landlord to the welfare of his tenant, or even to the state of his property, so that the annual subsidies be forthcoming. Even yet, on the estates of some of the noblest families in Rome, the utmost wretchedness and misery prevail without a thought for their amelioration. Nettuno still maintains its Mediæval character not yet touched

by modern alterations. Its principal building is an old fortress of the sixteenth century, seen on entering the town. It is a solid and substantial structure built of stone and brick. It is surrounded by a moat, now drained, which is crossed by a bridge of masonry in place of the vanished drawbridge. It is surmounted by guard-houses and watch-towers, and flanked by a low terrace facing the sea. There is also a crumbling, old castle bearing the arms of the COLONNAS. Mediæval walls surround the town. All these are worn by the weather, corroded by the sea winds, and more or less in a state of picturesque decay. Some old houses present interesting and architectural features, with windows divided by twisted mullions and quaint doorways. Tablets are also let into the walls with devices and mottoes—all wasted under the dissolving hand of time. Some of the nooks and corners offer excellent subjects to the painter, with their play of light and shade and groups of characteristic figures.

Before leaving this interesting spot, I should like to convey to the reader a more vivid picture of its present aspect. For this purpose we will take our place in the centre of the bay on the little pier erected for the lounge of the bathers. In front is the open sea. To the right is the headland, upon which stood a good part of the ancient city. It is now crowned by a modern lighthouse and a Papal villa. Beneath this is the quay and its white houses, from which runs a jetty which forms the modern harbour, such as it is. The little town stretches from the quay inland. Between the sands of the bay and the rising ground, somewhat removed from it, a dusty road runs and the railway. From the wooded uplands beyond the Borghesi mansion arises, with other buildings, mostly in a state of progress. To the left the view is exceedingly fine. A mile away the fortress of Nettuno frowns upon the waves, behind which the white buildings of the town arise, overtopped by the arched façade of the church, an artificial structure elevated above the roof with a campanile beside it. Stretching beyond the town, and seven miles further along the coast is seen a thin strip of land upon which stands the white tower of Astura, a place also of classic memories. Further still the headland of the Circeian promontory rises from the sea like an island, the fabled seat of the enchantress who changed her votaries into animal forms; and furthest away the Volscian hills, vague in atmospheric blue. The scene immediately before us is scarcely less enchanting as the afternoon sun begins to sink. The waves seem interwoven with saffron and purple and blue, as the fishing-boats with white lateen sails bend over the water, dipping their snowy wings into cool shadow. Everything seems bright, animated, vivacious. Let us leave the prospect ere the shades of night descend and blot it from view.

#### SIGNOR DUPRÉ'S THOUGHTS ON ART.\*

ONE of the attractions by which the promoters of the Crystal Palace at Sydenham expected to gain money for the shareholders was the collection of casts of modern sculpture. A good deal of care was taken in the selection. Among the works by which Italy was represented was *The Dead Body of Abel*, by Signor GIOVANNI DUPRÉ, of Florence, of which the following official description was given:—"As a representation from nature this statue has great merit, and it is interesting as the first work of a young Florentine sculptor, whom it raised to deserved reputation. He and his wife almost deprived themselves of food in order to procure the material in which to model it. When exhibited, it was ordered by the Grand Duke, about 1846." An advertisement of this kind ought to have made the fortune of a sculptor, but the truth is that modern Italian work is at a discount, and it is only exceptionally popular works which obtain high prices from English patrons. It is not surprising that Signor DUPRÉ felt a complacency that was pardonable when he saw his statue in such good company at Sydenham, and it was no less natural that he ran the risk of imprisonment by breaking one of the fingers, which had been made by some other sculptor. He only escaped by modelling a substitute on demand and repairing the cast in the presence of the officers. The incident is suggestive and characteristic. Signor DUPRÉ is entitled to be ranked among the leading modern sculptors; his style is marked by its

realism, and the addition of a finger which had the last phalange much too short was in his eyes a sort of sacrilege. The impulsiveness which moved him to break the law at Sydenham has likewise made him publish an autobiography, and it must be admitted that in both cases he was right. His book will hereafter be considered as interesting as BENVENUTO CELLINI'S, and, if fewer adventures are related in its pages, it is because it has been written in the nineteenth instead of in the sixteenth century. Signor DUPRÉ'S aim is to write about himself with impartiality; he never exalts his powers or tries to diminish the reputation of his rivals; and, indeed, if he is ever severe, it is when he is passing a judgment on himself. The book is a picture of a simple, manly artist, who has been inspired throughout his long career by a high ideal of his art, and has worshipped sculpture for its own sake, rather than for the money or the honours which he had derived from it.

GIOVANNI DUPRÉ was born in 1817 in Siena, where his father was a journeyman wood-carver, apparently of no great ability, and therefore badly paid. When the elder DUPRÉ went to Pistoja in search of better employment the boy accompanied him, and on an emergency was found to be more competent than his father to model heads for a showman's puppets. In time he was apprenticed to a firm of wood-carvers, and passed from one master to another in Florence, Siena, and Leghorn. But he was also enabled to study in the public galleries, and was recognised as a skilful youth. His shopmates called him "the poet." His wages were about three pauls a day, out of which he reserved a few sous to buy paper, pencils, and books. But although DUPRÉ could be called a model apprentice he was not without faults. He confesses he was justly caned in the school of art for tricks, and he was once locked up for assaulting a man who insulted him. As a professor he believes that the bodily chastisement of students might be profitably reintroduced into art schools.

DUPRÉ in his nineteenth year married a laundress, and then he resolved to become a sculptor. Every spare moment was given to study, and in 1838 he was able to send a statuette in wood to the exhibition. The subject was *Santa Filomena*, who was represented with one hand on her breast and the other holding a bunch of lilies, with an anchor, the sign of her martyrdom, placed at her foot. It was admired by a Russian, but he insisted on the removal of the lilies, and the statuette was thus transformed into *Hope*. In spite of this success DUPRÉ received little encouragement. He was not considered sufficiently competent to be allowed to work as a hewer of marble in a studio, and a professor who saw him copying spoke of his prospects as hopeless. However another professor advised him to take part in the triennial competition, and he was fortunate to be successful in a sort of way. He received ten votes, his rival four, and eleven of the judges voted for a division of the prize. But so much success was grudged him, and it was alleged that his relief was not the work of his hands, but of a professor's. To convince the sceptics, he attempted a statue of a *Bacchus*. He was incompetent to set up the irons; in a little time the model fell to pieces, and the experiment gave rise to more doubts about his competence.

While DUPRÉ was depressed in mind a new competition was announced which was to be restricted to natives of Siena, the prize being a pension which was to last for ten years. Just as he had prepared for the struggle he was officially informed that the money had been appropriated to a chair in the University. In his rage he destroyed his work, although afterwards he expressed gratification at the result, as the prize might have kept him idle. Next he resolved to undertake a life-size figure of *Abel*. But he was too poor to continue the work, and accordingly DUPRÉ appealed to the Florentines to subscribe forty francs a month for a few months. He did not receive half that sum. When the statue was exhibited it caused great excitement. DUPRÉ'S enemies were, however, ready for an attack upon it; this time the realism and accuracy of the work were turned against the sculptor. The statue was said to be a mere cast from the life, and the model was obliged to assume the position of the figure and submit to measurement in order that the truth of the statement might be tested. But the merits of the work overcame all opposition, and DUPRÉ was able to obtain a commission for it and a companion figure from a Russian grand duchess.

His success henceforth might be considered assured. DUPRÉ was soon afterwards elected a professor in the Florentine Academy, and on visiting Siena he was lionised as a celebrity. A commission was given to him for a statue of

\* "Thoughts on Art and Autobiographical Memoirs of Giovanni Dupré. Translated from the Italian by E. M. Peruzzi. William Blackwood & Sons.

*Giotto* for the Uffizi, and this gave him especial delight, for it was an opportunity for the display of realism. Signor DUPRÉ's book is not only an autobiography, but a collection of thoughts on art which have been suggested by circumstances in his own career. Here is what he says about the relation between naturalism and idealism:—

Some reasonings by my friends, certain articles as well as the compliments and eulogies of my statue of *Innocence*, finally persuaded me that there does exist a *bello ideale* impossible to find in nature, and this beauty should be arrived at by an imitation of the antique, and by the aid of memory. Nothing is more dangerous than this theory. Beauty is scattered over universal nature. The artist born to feel and perceive this beauty (which is the object of art) has his mind and heart always exercised in seeking it out and expressing it. He discerns in nature one or more living forms that in some degree approximate to the type he has in his mind, and the reality of these, by strengthening his ideals, enables him to work the latter properly out. The artist who is without his ideal, and forces himself to find it outside of nature, torturing his memory with what he has seen or studied in the works of others, makes but a cold and conventional work. The animating spark, the heat, the life, does not inform his work, for he is not the father but only the stepfather of his children. To this school belong the imitators, that is, the timid friends of nature. On the other side, but in much greater numbers, and with much greater petulance, are the *naturalists* who despise every kind of idealism, and especially despise it because they have it not. Neither is their heart warmed by strong and sweet affections, nor do they with their eyes or their minds seize, among the multifarious shapes of nature, a type, a movement, or an expression which, assiduously pursued, awakens and fecundates the idea within them. The first ruffian or harlot of the streets, taken by evil chance, suffices for them, and they delight to drag this noble art of ours through filth and ugliness. Each of these extremes I have sought to avoid; but it is none the less true that I was carried a little away by the discoveries and writings of literary men and critics of art on the road that leads to the conventional and academic.

The two principles of idealism and realism were much discussed at that time in Italy. To show the lengths to which the advocates went, it is enough to mention that OVERBECK used to maintain that models and nature were destructive of the artist's idea. The principal quality in the work of art was supposed to be the original conception, and accuracy was said to be an enemy to its expression. On the other hand, the *naturalists* were opposed to beautiful forms, and gave a preference to models that were without grace. In fact on one occasion BARTOLINI, who was the principal professor in Florence, introduced a hunchback as a model into his classes. It is no wonder that with such influences we see so many aberrations in the Italian department of international exhibitions.

Professor DUPRÉ was among the competitors for the Wellington Monument. He says that he hardly remembers his design, but he believes that at the angles of the lower base there were groups which symbolised *Military Science*, *Political Science*, *Temperance*, and *Fortitude*. The four faces were filled in with *alto-relievi*. On a pedestal was the principal group of *Wellington with Victory and Peace*. It is not easy to imagine whether the work was possessed of much merit, but as it was broken to pieces in the passage to London, it appeared under disadvantages. On the occasion of his visit to London DUPRÉ made the acquaintance of Baron MAROCHETTI, who declined to enter into the competition. We are told that the Baron was in the habit of employing men to make his clay models, and as they belonged to different schools it was impossible to insure uniformity of style. He was also an advocate for tinted sculpture. JOHN GIBSON also upheld the principle. His *Venus*, which was exhibited in 1851, was rather delicately coloured; but Signor DUPRÉ says that there was a *Cupid* by GIBSON which had golden hair, blue eyes, wings with tufts of red, green, blue, and orange feathers, and a chiselled and gilt quiver. Among the moderns, PRADIER was the only sculptor who knew how to use colour with discretion.

Honours came fast on Signor DUPRÉ after his return to Italy, and he received many important commissions for public statues. His eminence was recognised when he was elected president of the section of sculpture in the Vienna international exhibition, but, like many other artists, he is sceptical about the advantages of those gatherings. At the present time he holds an enviable position in Italy, and a man with so much goodness of heart deserves all that his country can bestow.

## THE INTERNATIONAL HEALTH EXHIBITION.

SINCE our last report many additions have been made to this exhibition, and it is only within the last few days that several arrivals have been placed in position. These include the exhibits from Siam and many from Japan. The Tartar horses and mares are among the recent arrivals, and are accompanied by natives in their national costumes. Messrs. Warner & Sons, of Cripplegate, have erected one of their noted windmills in the grounds on the left hand side of the south gallery, and the sanitary and insanitary houses that have been so long in hand are at length opened to the public. The late visitors are, therefore, in a better position to view the exhibition in its entirety than were those who saw it at an earlier date. There is no falling off as regards numbers, notwithstanding that London is supposed to be empty; on the contrary, with the exception of Wednesday, the half-crown day, they are rather on the increase, and the cry is "still they come." Excursion trains at low fares from all districts within fifty or sixty miles of London, enabling country cousins to "do" the exhibition in a day, are about commencing, and the probability is that the last days of the exhibition, whenever they may arrive, will see larger numbers within its walls than at any other time. There is probably no country where such a number of cheap toys are to be seen in the streets as in England, although many of them are of foreign manufacture; and the "intelligent foreigner" cannot but be struck as he walks up the Exhibition Road with the number of itinerant vendors of useless productions who are rather importunate in their desires to dispose of their wares. From one penny to sixpence a little museum of curiosities may be purchased, ranging from Bradlaugh's baby, warranted not to cry, which, however, strangely belies its facial expression, to exhibition alligators, albeit of a harmless character, that require to be wound up ere they will move, when they perform gyrations on the pavement to the evident delight of "Young England." Inside and out the attractions are "immense," and although we are said to be a nation of grumblers, certainly the Health Exhibition of 1884 is doing its best to repel the accusation.

The shops in the old London street are now in full working order, and with the attendants and workers dressed in the costumes of the Middle Ages are a great source of attraction. From the point of view most likely to interest the readers of *The Architect*, the wrought-iron worker's, represented by Messrs. Starkie Gardiner & Co., of the Thames Embankment, claims attention. An Englishman of the most ordinary attainments can generally appreciate hammered iron work even of an ordinary character, but when one finds an amount of artistic feeling embodied in the productions, this appreciation gives place almost to enthusiasm. The industry, which has lain dormant for such a length of time, is now fairly resuscitated, and we cannot be surprised at anyone of taste or education preferring many of the articles as here shown, and wrought of this humble metal, in place of the more showy ones manufactured of the more costly kinds. Over the entrance to this Mediaeval workshop is written the legend, "By hammer and hand all arts must stand." This and similar mottoes appears to have been generally adopted by iron workers. We do not know if this sentence has been culled from the arms of any company or guild, but a very similar one is the motto attached to the Smith's Arms of Nottingham, which consists of a chevron and three hammers, ducally crowned, "By hammer and hand all arts do stand" being the accompanying words. The motto is certainly most appropriate, though it may be equally applied to other metal trades. The firm have also recently erected an old smithy in the open space beyond the further end of the street, where some craftsmen are daily to be seen at work.

Mr. Henry Charles Stephens.

STEPHENS'S stains for wood have now a world-wide popularity, and those who are unacquainted with what they are capable of accomplishing may see for themselves at Stand 874 in the east gallery. The effect of these stains on white woods in producing the appearance of mahogany, walnut, satin, rosewood, &c., is well known to many of our readers, and is shown here; but valuable as these stains are for the many purposes to which they may be applied, not forgetting flooring (and we may remark that these chemical productions are stains in the proper acceptance of the term) they are capable of a higher class of artistic work than mere self-colouring. Here we see panelling of a most artistic character, treated entirely by Stephens's stains; as, for instance, a "Sheraton," one of the most difficult classes of ornamentation perhaps to treat in such a manner, as well as "Chippendale" and other designs; in fact, with an artist of skill and taste, there appears to be little that these stains are not capable of accomplishing.

Messrs. Burke & Co.

At Stand 896 in the east central gallery, Messrs. BURKE & CO., 17 Newman Street, W., and Rue St.-Luc, Paris, have a choice set of specimens of mosaic and marble work, the former predominating. The largest, and we may say the principal feature, is a slab of mosaic work, containing a life-size portrait of "Justice." This is a fine production, and has, we understand, been made to order. It

is composed exclusively of natural coloured marbles. The background is a deep-coloured dull yellow, which brings out the drapery of the figure in the best manner. This is of various shades of red, the brightest assimilating somewhat to a dull terra-cotta, and is the principal one in the figure save a neutral-coloured flowing green scarf. It is a decided work of art, and of itself sufficient to maintain the reputation of the firm. There are several slabs or panels, reproductions of old Pompeian and Roman originals, excellently portrayed, and a few specimens of Pompeian pavement in black and white, in a good state of preservation. Many specimens of natural marbles are also exhibited, amongst which we notice a small slab of onyx, with an exquisite sea-green tint running through a portion of it. The dados of marble are rich in colour, and there are two examples of balusters in different coloured marbles of a massive character. Though small as regards size, like many of the exhibits, it is rich as regards its artistic features.

*The United Asbestos Company (Limited).*

The productions of this company, of 161 Queen Victoria Street, E.C., are to be seen at Stand 864 in the East gallery, and are interesting as showing to what important uses this mineral, virtually a stone, has by the aid of science been shown to be capable of adapting itself. Looking at the mineral in its natural state, and then turning our eyes to its many adaptations, we cannot be surprised at the expression of wonder to which some persons give vent on looking at them. From a crude, little understood material, in use a quarter of a century since for fuel for gas stoves and a few other commonplace purposes, it has become a most important material in a variety of ways. It has proved itself to be most valuable as a paint, resisting the encroachments of fire to a great degree, and the whole of the wooden buildings at the exhibition have been painted with it. The asbestos paints are also non-poisonous, and therefore valuable as a sanitary agent. It is also made into millboard of such a thickness that it has become a reliable agent for fireproofing floors and wooden partitions. It in addition has become to be extensively used as a packing for steam joints, piston-rods, &c., and in the form of "washers" is extensively used for machinery. But a great stride was undoubtedly made a year or two since when it was found to be capable of being woven as a fibre, and as a result of this, the company exhibit a complete fireman's suit of asbestos cloth, non-inflammable, while fireproof ropes for fire-escapes and such purposes are now made in any quantities. Another use to which it has been found applicable was discovered by M. Maignen, the inventor of the "Filtre Rapide" (a description of which has appeared in our columns), who, after experimenting upon different kinds of textile materials for the base on which to rely to form the body to which his filtering media should rest, and finding all of them imperfect, tried as a last resource the woven asbestos cloth, which has proved to be the best possible for the purpose.

*Mr. Samuel Putney.*

One of the most recent additions to the exhibition is to be found in a suite of apartments on the left-hand side of the south gallery below the dairies (in which Mr. Taylor Smith's electric lighting apparatus is shown) the flooring of which introduces us to a somewhat novel arrangement for laying boards. This is the invention of Mr. SAMUEL PUTNEY, timber merchant, of Baltic Wharf, Harrow Road, Paddington, and is well worth a close examination. Although it cannot be adopted for the cheaper class of flooring, it is none the less to be commended whenever it can be used, as beyond its novelty it insures a substantial groundwork, as nothing less than one-inch boards can well be used. It is called a "nail-less" floor, and it may really be used without a single one being inserted, but as a matter not altogether of security, but to prevent any "rising" or creaking of the floor, a few here and there may be an advantage. But the nails if used are not visible to the naked eye, as will be seen by our illustrations which show merely the sectional view, as the central one may be

an ornamental flooring of the parquet character, at a much cheaper rate than is now charged. His designs are certainly somewhat restricted, as they must be of the "ribbon" or plain longitudinal character, but with different coloured woods a very pretty effect can be obtained, and this may be diversified by adopting squares or diamonds of a certain size. Mr. Putney has prepared another section besides the one illustrated, with a right-angle shoulder, which is recommended for common floorings, but we have a decided preference for the acute angles. It is maintained that by using Putney's patent boards the shrinkage or buckling so often complained of in parquet floors is avoided, and that they can be taken up and relaid without injury. Mr. Putney has supplied the flooring for Madame Tussaud's new exhibition building in the Marylebone Road, and no better test could be obtained for it. In addition to the flooring, the invention is also adapted for wainscoting or dados, and we subjoin a sectional illustration of the

pattern usually used. Amongst other uses the new flooring will be found of much service for laying down in temporary rooms, or for special purposes in any building, the ease with which they can be laid and taken up, coupled with their attractive appearance, being a great recommendation.

*Messrs. C. Isler & Co.*

At Stand 460 are appliances without which an exhibition bearing the title of the present one would be anything but complete, seeing they affect the vexed question of pure water supply. Messrs. C. ISLER & Co, 88 Southwark Street, S.E., are the exhibitors, and the exhibit comprises Artesian-bored tube wells and various pumps for raising the water when the well is sunk; also various boring apparatus, such as is used not only for Artesian wells of any depth, but for hydraulic lifts. Amongst the contracts recently completed by this firm was a well for the E. C. Powder Company's New Works at Bean, near Dartford, which yields at the rate of 2,500 gallons of water per hour. A very important feature in favour of Artesian wells is that they are as economical for small supplies as for large, and are as applicable for domestic as they are for public use. The consequence is they are yearly coming into more general favour, and for villages and places where no public waterworks exist, and the inhabitants are dependent for this first necessity of life upon the ordinary well, into which the cesspool too commonly filters, they must be looked upon as an undoubted boon. To exemplify this, Messrs. Isler have driven one at their Stand as above, and, by means of a common lift-pump, procure water from a depth beyond all chance of contamination. The firm also manufacture registering turnstiles, and their contributions are well worth examining.

*Messrs. Mappin & Webb.*

Adjoining the last-named is the exhibit of Messrs. MAPPIN & WEBB, of Oxford Street, who, as agents for the patent Abbotsford grates, are not behind their competitors in the beauty of the articles they exhibit. The Abbotsford grate in its different forms is the only one exhibited, but some of the designs are equal to anything in the exhibition, while the collection deserves high commendation. A unique suite, named "Ye Chimnie Corner," will possess attractions for many, as it carries an air of comfort and cosiness about it for a cold winter's night. A kind of alcove, supported by pillars, is built out from the chimney breast, and this holds a settle-cushioned seat on each side of the fireplace, though "who shall be first" to secure the "coign of vantage" is likely to prove a discursive element in a large family.

*Messrs. Yates, Haywood & Co.*

At the entrance to the east central gallery stands the exhibit of Messrs. YATES, HAYWOOD & CO., of Upper Thames Street and the Effingham Works, Rotherham. This collection is of a similar character to that shown by the firm at the recent exhibition of building appliances at the Agricultural Hall, and include grates, mantels, and the usual surroundings of the fireplace. This firm have recently paid considerable attention to iron mantelpieces and overmantels, and the examples now shown evince much merit, and the

nailed to the joist as shown, but the right-hand one covers it, so that no nail is seen on the surface, and being tongued or grooved, and very accurately made, they may even be slid into their position, and a close and even surface is presented at the top of the floor; thus a saving of time, labour, and expense is gained, and by using the section of board we have illustrated accumulations can scarcely take place in them, and exhalations from lower floors are retarded. But beyond this Mr. Putney's idea has been to introduce

colouring is good. Most of the grates exhibited are of elaborate make, and rich painted tiles enter into their construction largely. This avenue certainly contains the richest specimens of *articles de cheminée* in the exhibition, and it is difficult to say to which firm the palm should be awarded.

*Messrs. Beynon & Cox.*

The question of baking bread by means of gas fuel is one that has been strongly advocated by the Smoke Abatement Institution, the first oven heated by gas suitable for a baker having been exhibited at the Smoke Abatement Exhibition held here in 1881-2. The oven in question, like many first attempts, was rather crude in character, but in the interim improvements have been made, and the firm mentioned above (of Torquay) have also entered the lists as manufacturers of bakers' ovens heated by gas. We have called attention to the productions of this firm for cooking by gas on previous occasions, their principle being the applying the heat from the outside of the roasters or oven, and collecting the atoms in a chamber at the upper part where it is superheated, and can only escape by descending to an even lower level than where it was first admitted. Now, although we are not amongst those who consider there is anything injurious to be feared from the admission of the burning gas into the cooking chamber, if it can be done without so much the better, and this Messrs. COX & BEYNON have, during the last four or five years, clearly demonstrated, carrying on their operations at as small a consumption of gas as most of their competitors, and providing a copious supply of fresh air to the oven at the same time. The gas bread-oven recently introduced and patented by them is carried out in a similar manner as regards the non-admission of gas to the inside. In the portion of the exhibition devoted to the bakeries, off the south gallery to the right, one of these ovens is at work baking bread, cakes, &c., from "early morn till dewy eve," and Messrs. Bertram & Roberts, the refreshment contractors to the exhibition, were so pleased with it that they had one sent to the camp at Wimbledon, which was in use during the whole time of the rifle competition. This oven has much to recommend it. As may be seen by our illustration, it is of a portable character, that is to say, it requires no fixing, and may be made to run on wheels for transportation, and under certain conditions may be used as conveniently in the open air as in a covered building, all that is necessary being to carry the gas to wherever it is set. The one in question may be termed a three-decker oven, that is, three ovens deep, each one having two tiers of shelves, and the entire three or either of them can be used at

pleasure, as by means of dampers or side-valves the heat can be concentrated to where it is required, and the outlet for the products of combustion is shown at the lower portion of the apparatus in the centre, there being a corresponding one on the other side. The advantages of this gas bread-oven may be described as follows:—Wherever gas can be obtained this oven can be utilised, and any ordinary business premises may be turned into a bakery. Then we do away with the smoke nuisance, and it is an admitted fact that bakehouses, as at present constructed for burning coal, are the greatest obstacles to the elimination of smoke. A public advantage would thus be gained if bakers generally were compelled to burn gas. From the baker's stand-point the advantages are as great. Apart from the general cleanliness attendant upon gas when used as a cooking agent, there would be a great saving of labour, as well of time, for as regards the latter, there is no necessity for the oven to cool between batches; thus "heating-up" for each fresh batch is obviated, consequently a much greater amount of work can be obtained from it. In the cost of fuel, a point that the baker will look at spite of any other advantage, he will find a decided saving, and the most sceptical must be convinced when the gas account rendered to the firm by the gaslight and coke company who supply the exhibition is shown him. It will be seen, then, that besides the public benefit there is a "pronounced" pecuniary gain, from each point of view, to the baker who adopts gas baking-ovens on Beynon & Cox's principle, and so far as the baking is concerned, the most sceptical must admit, as he sees the contents turned out of this oven daily, that it is as well done as by the most approved coal-oven in the market.

## SANITARY AND INSANITARY DWELLINGS.

THE two houses which have been in course of erection for some time past on the right hand side of the open space leading to the central gallery, at the Health Exhibition, South Kensington, have recently been shown to the visitors, although at the time of opening, and even at the moment we write they are not quite completed. They are of course not intended to educate the classes who form the readers of this journal, but will no doubt be an attraction to a large number of that section who go to the great show-grounds determined to see everything, and to whom private apartments are not sacred provided they can gain access to them. There are no new ideas that we can see enunciated in the arrangements of these two houses. The old proverb that "extremes meet" is certainly not correct in this case, for a wider departure than is to be seen between the two can scarcely be conceived. In holding these mirrors up to nature it need scarcely be said that those to whom the idea was entrusted to carry out have in the one case selected the worst systems and appliances, and almost gone out of their way to make every arrangement as bad as it could well be, and that would scarcely be indulged in by the most advanced of jerry builders, while, on the other hand, the most modern and best appliances are used, showing the two in the strongest contrast. We enter the insanitary house at the basement, and when we reach the top floor we pass into the "perfect" one, and down to the basement, so we cannot by any possibility miss any of the lessons intended for our learning. Entering then through the front area, we find the dust-bin in the position it is too often fixed, viz., against the wall of the house, and near to window or door. The walls of the kitchen show the damp arising through the absence or inefficiency of a damp-proof course, and reaching the scullery, we find the sink in a corner where little light and no ventilation is near it. The waste or overflow-pipe is connected with the drains (unventilated, of course) by means of a common "dip" trap; and here, too, we see the connection of the pipes passing through the interior of the house with bad joints and junction. The joists of the floor rest direct upon the ground. The cisterns—two in number, one in the roof and the other on this floor—and the waste-pipe from each is taken directly to the drain. The one on the kitchen floor is in a most awkward position, with the D-trap of water-closet directly over it. The servants' water-closet is placed under the stairs without light or ventilation, and is of the oldest-fashioned type. Reaching the ground floor we see the soil-pipe again in its passage from the upper storeys, and, if any leakage or defect occurs, we know what the result will be. There is a water-closet on this floor, and it is placed in an objectionable position, and dependent for its light from a window opening on to the staircase, thus contaminating the air of the house. A small commonplace lavatory is fixed in an adjoining chamber, and the waste from this is carried into the D-trap of the water-closet. The next floor—which would be the drawing-room floor in a good house—is omitted from these buildings; on the plea that sanitary appliances are rarely to be found in them, and we proceed upwards to the bedrooms. Here is another water-closet placed under the stairs, opposite the bedroom doors, and, of course, without light or ventilation, ill-applianced, and open to the objections mentioned in the others. A service-box from the cistern in roof supplies this, and the effect upon the water in the cistern generally, from the arrangement of the closets, can be easily imagined, and the partitioning under the seat being unplastered, admits the foul air into the adjoining rooms. Close to the last-named water-closet, and also in a dark confined space, is a servants' slop-sink, the waste-pipe again being carried to the D-trap of the water-closet, and in close proximity we find the bath splendidly ill-constructed. It has no overflow-pipe, and the inlet and outlet orifice is one and the same, so that soap-suds, &c., are returned into it whenever the water is again turned on. This waste-pipe is also connected with the D-trap, and can scarcely be said to be trapped at all; and there are other unsanitary features in connection with it that may be readily assumed by the reader. Reaching the attic we see the cistern, which is made of deal lined with zinc, and the arrangement for supplying the water-closet by the service-box before mentioned. Just outside the dormer window we see the rain-water pipe, which also forms a portion of the soil pipe, a nice accompaniment to our breath of morning air. So far as the other appointments in this house are concerned, they are neither better nor worse than are to be found in thousands of others; and if they cannot be countenanced from an hygienic point, they are certainly not so dangerous as what are generally understood as the sanitary arrangements. The grates and their surroundings are of the ordinary type; it is lighted with gas on the usual plan, a gas stove (unventilated) provides heat to one of the rooms, and the walls are papered with the old-fashioned arsenical wall-papers. We presume, too, to make the *tout ensemble* complete, that the paint used throughout the house is of a poisonous character; but on this head we have no information. There are several details as regards the effects likely to be produced upon health owing to the manner in which the fittings are carried out that we need not stop to discuss, as they have doubtless ere this suggested themselves to the reader, and where everything is pro-

fessedly so bad it is perhaps not complimentary to mention the names of the firms who supplied the work; but as, we presume, they worked to order and are capable of better things, we may mention that of Mr. J. R. ROBERTS, Harrington Gardens, South Kensington, as having provided the general structure, and most of the plumbing and drainage work.

Crossing a passage from where we recently stood, we come upon the third or attic floor of the sanitary house. Here of course all is *couleur de rose*. We find here a well-ventilated and light cistern-room containing two good-sized cisterns, one for drinking water exclusively, and the other for general domestic and sanitary purposes. Messrs. BOLDING & SONS, South Molton Street, W., have supplied these, and they are fitted with overflow pipes, discharging into the open air, and entirely disconnected from all drainage, and they are each fitted with a plug and chain for emptying and cleansing. In all parts of this house wherever a draw-off tap is fixed, it is supplemented with a stop-cock above it, to enable the water to be turned off should the draw-off tap require repairs or leakage occur in the pipes. While on the subject of the water supply, it is as well to mention what are the opinions of the "powers that be" on the subject of the purity of water. There is not a water filter in the sanitary house, and the argument used is that if the water is delivered pure, it should be kept so by paying proper attention to the cisterns in which it is stored. Considering that we find Maignen's water filters erected all over the grounds by the authority of the executive, this seems somewhat of an anomaly, and although we are free to admit that London water is far better than that of most places when delivered to us, we demur to the idea that it is pure, and we also consider that it would be dangerous even in the best regulated household to rely upon the cistern being kept as scrupulously clean as would be necessary to keep the water in as good a state as when delivered. This would require a cistern to be emptied every day or two at the least, and the waste of water would be so enormous that the water companies would soon endeavour to put a stop to it. We cannot imagine this to be the collective opinion of the executive, and we imagine few medical men could be found to endorse such a view. Ventilation is carried out pretty freely all over the house, both inlets and outlets being used. The firms who have supplied them are Messrs. KITE & Co., Chalton Street, N.W.; Mr. EDWARD WOOD, Red Bank Works, Manchester; while Messrs. STRODE & Co., Osnaburgh Street, N.W., have fixed Harding's air-diffusers, an inlet ventilator in which the air is "filtered" before entering the apartment. An excellent system of vertical inlet ventilation is carried out in all the windows, which have been made under the patent of Mr. R. ADAMS, of Great Dover Street, S.E., a system that most of our readers, we suspect, are conversant with. We allude more particularly to the swing sashes, enabling the windows to be entirely cleaned from the inside, and so avoid accident. The ventilation before alluded to consists in having a deep bottom bead on the sill of the frame, so that by raising the bottom sash a few inches air is admitted in an upward direction (the proper way) between the meeting rails of the sashes in the centre, and without draught, the bottom of the window frame being still closed, not having been raised above the deep bead. This kind of ventilation may be indulged in with perfect safety against the window being opened from the outside, as it is secured by a new patent fastener of Mr. Adams's invention. This consists of spring bolts fixed on the upper rail of the lower sashes, with the points towards the sides of the top frame. Into these plates are set having three or four slots, and, according to the height the lower sash is lifted, so the bolt enters one or the other of them. Some of the other windows that cannot be so easily reached for opening are actuated by cords with patent self-locking apparatus at the sides, and these again cannot be "operated" upon from the outside. Gas is laid on throughout the house, the fittings having been supplied by Messrs. FARADAY & SONS, Berners Street, Oxford Street, and they are all supplied with ventilating tubes to carry off the products of combustion. The electric light is also being fitted up in it by Messrs. WOODHOUSE & RAWSON, 11 Queen Victoria Street, E.C. Descending to the next floor, we notice a housemaid's sink provided by Messrs. CLIFF & SONS, of Wortley, Leeds, made of the enamelled stoneware that is a speciality with them. The water-closet is a wash-out, contributed by Messrs. SCRIVENER & Co., Fitzroy Road, Regent's Park, who have also supplied the pan-closets, soil-pipes, some of the sinks, and other material. The bath-room adjoining has been fitted up, as regards the appliances, by Messrs. BOLDING & SONS; and we need scarcely add that their most approved fittings have been used; that everything has been done in the surroundings of these three very necessary apparatus to render them as perfect as possible, and they are planned so as to be shut off or practically separated from the sleeping apartments. The floors generally are of parquet, as offering the best from an hygienic standpoint. The apartments call for no particular remark beyond what applies to our prior observations as to the general arrangements. All the wall-papers used are of course non-arsenical, and are of the low-toned colours now in vogue. The stove grates—rather æsthetic in character—wood chimneypieces, and tiles have been sent by Messrs. SHUFFREY & Co., Welbeck Street, Cavendish Square, the marble chimneypieces and fancy tiles coming from Messrs. E. & C.

BRABY, Belvedere Road, Lambeth; and here we may remark that the joiner's work, papering, painting, and decorating was carried out by Mr. GEORGE HOWE, 41 Wigmore Street, W., the paint used being that of the Patent Liquid Fireproof Cyanite Co., being a fire-resisting paint for woodwork. Passing to the ground floor (the drawing-room floor having also been dispensed with here), we find the water-closet fitted with Tyler's waste-preventing valve, fitted by Messrs. DENT & HELLVER, of Newcastle Street, Strand, supplied by a separate cistern, soil-pipe carried outside, ventilated at top and bottom, and a lavatory adjoining, carefully secured against nuisance of any kind. We now descend to the basement, containing the usual appendages of scullery, sink, servants' water-closet, &c., all of the most approved character. Some of the water-waste preventers have been fixed by Messrs. PURNELL & SON, Vincent Street, Westminster, and are on the syphon principle, and others were supplied by Mr. O. D. WARD, of Upper Thames Street, E.C. Thus in numerous instances types of various well-known and reliable appliances have been selected in preference to confining them to one make, which would not have been generous to other makers. The plate-glass used in the windows was contributed by Mr. WILLIAM RAMSAY, of Farringdon Street, E.C. The only other feature of interest within the house that we have not mentioned is one of Messrs. DOULTON & Co.'s open fire, ventilating, fire-clay stoves, and the same firm provided a vitrified damp-proof course for the walls. Passing into the back area, we find air bricks supplied by Mr. GEORGE JENNINGS, of Lambeth, to ventilate the joists under the basement floor, and the cast-iron system of drainage shown, the joints being made with lead, and the pipes contributed by Messrs. R. LAIDLAW & SON, Little Bush Lane and Alliance Foundry, Glasgow. A large disconnecting chamber is shown into which all the pipes enter, and so on to the main drain, and this disconnecting chamber is also ventilated by an adjoining air inlet, which allows the air to enter the chamber along the drains and up the soil-pipe. All connection between the house and the drains is cut off by means of a syphon gully trap, of Messrs. BAILEY & Co., of the Fulham Pottery, S.W., who have in addition supplied some of the other drainage appliances. The area, which is of the usual width, is lined with the fine white-glazed bricks manufactured by Messrs. CLIFF & SONS, Wortley, Leeds. It must of course be understood that the framework of these houses is of wood, and they have been covered with HITCHING'S patent fire-resisting plaster slabs supplied by the company, 1 Gresham Buildings, Basinghall Street, E.C. These slabs, mentioned in a descriptive notice in *The Architect* on a previous occasion, enabled the work to be completed in a much shorter time than would have been the case had any other medium been employed. One other meritorious feature deserves mention, and that is a portable galvanised iron dustbin, supplied by Messrs. T. H. PEIRCE & Co., Weymouth Street, Portland Place. There are at the moment we write one or two rooms in the basement not yet complete, and one of these has very much the appearance of what a dining-room should be, judging from the colouring and fittings; but as we are not in possession of information regarding them, we defer any remarks.

And now our description is finished. Judging from the *on dits*, the executive gave their consent rather grudgingly to the scheme (which originated with the Dwelling-house Committee), as from what we are told great difficulty was experienced by them in obtaining sufficient funds from the executive and suitable space on which to erect them. The absence of the "sinews of war" in sufficient quantity is thus mentioned by Mr. H. H. Collins, F.R.I.B.A., in a paper:—"The special committee had desired only to use such appliances as they were enabled to pay for, so that they might stand perfectly clear from all imputations of favouritism. Lacking funds, however, to proceed with the objects they had in view, they were forced to obtain the assistance—which was cheerfully accorded to them—of various manufacturers, but they impressed upon them that in using their appliances, they only employed them as being good types of such fittings as ought to be properly used in the construction of a sanitary house." Further on, he says that "the Special Committee would have desired to have given practical illustrations of good methods of heating, lighting, and ventilation, but the time and *means* (the italics are ours) at their disposal were quite inadequate to allow of their showing more than mere sketches of these details." Taking all things into consideration, and looking at what we may call the lukewarmness of the executive in the matter, we should not have been surprised had the "Special Committee" declined to carry out their idea, and we are inclined to think visitors would not have experienced a great amount of loss had the houses not been erected at all.

The Buccleuch Memorial Committee have requested Mr. R. Rowand Anderson, of Edinburgh, to prepare designs for the national memorial to the late Duke of Buccleuch. The execution of the statue, which is to be of bronze and of colossal proportions, has been entrusted to Mr. Boehm, R.A. The memorial is to be erected in Prince's Street Gardens, Edinburgh.

## NOTES AND COMMENTS.

THE unexpected success of Messrs. LEEMING & LEEMING in the competition for the Admiralty and War Office has given rise to the insinuations which are customary whenever an architectural competition has been decided. There are always busybodies who find it a duty to reveal how little a successful competitor has had to do with his design, and after listening to them it would appear as if the most incompetent men are invariably the winners. If the aid of an assistant has been obtained in the preparation of the drawings it is assumed that all the credit should be given to him. In Messrs. LEEMING'S case we understand that the prize was gained solely by the geometrical drawings, which were made by the two brothers, with the aid of their draughtsman, Mr. FARRAR, and that the perspective did not influence the decision. As sculpture had to be shown, Messrs. LEEMING were acting within their rights to employ the aid of a figure draughtsman, but to cavil on that account is absurd. It might almost be said, with as much reason, that a framemaker should not be employed to make the strainers.

THE meeting of the British Archæological Association will commence at Tenby on September 2, under the presidency of the Bishop of St. David's. An interesting programme has been arranged. Tenby itself has much to show, and there will be excursions, among other places, to the Edwardian House at Eastington, to Angle, of which GIRALDUS CAMBRENSIS was rector, to Stackpole Court, Carew Castle, Upton Castle, and Pembroke. Cromlechs, barrows, and various prehistoric remains are to be found in the district, and will receive attention. St. David's and the neighbourhood are among the attractions which are set down for the "extra days." Papers will be read at the evening meetings on "Manuscripts connected with Pembroke," "The Extent of the Ancient British Church," "The Municipal Records and Seals of Tenby," "Gumfreston Church," and "Manorbere Church."

SOUTH SHIELDS has been supposed to be a prosperous place; but, in spite of their shipping trade, the inhabitants consider themselves to be too poor to undertake the cost of erecting a town hall and municipal offices. That the buildings are needed is admitted. It appears there is only "a miserable and unsanitary place" to hold trials, and the officials are compelled to carry on their work with much inconvenience. A site that would answer belongs to the town, and if not approved another could be purchased without difficulty. But it would be necessary to undergo taxation for the erection of a building, and the fear of adding a penny to the poundage rates has overcome the wealthy merchants and shipowners. The Town Council are convinced of the necessity of new buildings, but have not the courage to carry out the duty which is entrusted to them.

THE power possessed by an architect in withholding a certificate is, from its magnitude, considered by lawyers to be inequitable, as it may be used to the disadvantage of a contractor. Happily the majority of architects are not so minded, believing with SHAKESPEARE that while it is excellent to have a giant's strength, it is tyrannous to use it like a giant. But the reverse occasionally happens. In the case of an unfortunate builder which last week came before the Glasgow Bankruptcy Court, the bankrupt stated that with regard to some work at Lamlash, "the measurements were sent to the architects in December last, and up to the present time they had neither approved nor disapproved of them, although bankrupt had repeatedly applied for them. He considered there was still a large balance due on the job. In consequence of not getting the measurements certified the firm fell into difficulties, having no money to pay their creditors." As the bankrupt's statement does not appear to have been disputed by the creditors, or contradicted by the architects, it may be assumed to be a correct description of the origin of his bankruptcy, although it is possible the amount of his "large balance" would be reduced on examination. The architects referred to by the bankrupt are Messrs. H. & D. BARCLAY, whose names are not unknown in law proceedings, as they were the architects of the Board school at Pollockshields, where, it will be remembered, the play-shed fell and killed four children.

THE Cathedral Commissioners have presented a report upon Manchester Cathedral. This building is in the somewhat anomalous position of being a parish church and a cathedral. The revenues of the capitular estates are so divided that it will be necessary to pass an Act to appropriate a sufficient portion to maintain the cathedral. Probably the easiest way out of the difficulty would be to erect a new building of which the city might well be proud, but it is supposed that the affection for the old church is an impediment. There is no reason why the church should not exist for parochial uses, but no restoration or alteration can make a cathedral out of it that will correspond with the present position of Manchester. The bishopric was founded in 1847, and since that time the Dean and Chapter have had much difficulty in arranging the affairs of so peculiar a trust.

THE eighteenth-century architects in England would seem to have been willing to recognise the principle of a division of labour when dealing with a client who was a nobleman. A curious story which illustrates this compliance was told by the Duke of BUCKINGHAM to a party of archæologists who lately visited Stowe. When Lord TEMPLE came into possession of the house he resolved to construct a large hall, a large portico, and a large flight of steps. The external work was entrusted to one architect to design, and the internal to another. When the plans arrived they were modified by His Lordship, and no doubt to the great delight of the courtly architects. In fact, Lord TEMPLE was the master mind, and the architects were mere assistants. It is not surprising to learn that, with such a client, the alterations occupied about twenty years, or that, as time went on, a great part of the house had to be sacrificed to the owner's love of dabbling in bricks and mortar. If the histories were as well known, a similar story could probably be told of many another house, and that the original unity of a dwelling was often destroyed in order to gratify an amateur.

IF students from the country wish to sketch the exterior of the Courts of Justice, especially on the northern side, they will find the present time favourable. The whole neighbourhood of Carey Street and Lincoln's Inn is now deserted. The opportunity has been used to carry out some works in the Courts. The pavement of the entrance porch has been taken up in order to approach the vaults where machinery for electric-lighting is placed. One work might have been well omitted, namely, the iron railing opposite St. Clement Danes Church. A screen existed there, but as it was a continuation of the line of frontage of the buildings, and the pavement was curved, there was a part of the flagging somewhat wider than the rest. This was an advantage; but, for some unknown reason, the width of the pathway was decreed to be made uniform, and, consequently, the railings were set up. There is, consequently, a double screen enclosing a piece of flagging; and, apart from the waste of material, the effect is unpleasant and injurious to the appearance of the Courts. It should be removed without delay.

A NEW variety of the competition system has been introduced in connection with the proposed Liverpool Cathedral. Architects who had designed churches—whether erected or not—were invited to submit drawings, which were to be referred to Mr. CHRISTIAN, in order that he might make a selection. It is understood that a very large number of designs were sent in. The architects who have been selected are Mr. PEARSON, R.A., Mr. BODLEY, A.R.A., Mr. JAMES BROOKS, and Mr. WILLIAM EMERSON, and they have been asked to prepare sketch designs for the cathedral. It is remarkable that not one Liverpool architect is among the competitors, although the project has been long studied in the city. It is also a surprise, considering the number of Classic buildings in Liverpool, that the Gothic style has been adopted, especially when it is known that the first bishop has no admiration for the symbolism which that style expresses.

BOXLEY ABBEY will shortly be sold by auction, and some interest attaches to this event. The abbey was founded about the middle of the twelfth century by WILLIAM D'IPRES, Earl of Kent. EDWARD II. took up his residence at this abbey during the siege of Leeds Castle in October 1221, from the refusal of its governor to provide lodgings for Queen ISABELLA and her suite when going on pilgrimage to Canterbury.

## ILLUSTRATIONS.

THE WATERING-PLACE.

WE publish a companion to Mr. BRIDGMAN'S eastern picture that appeared in last week's *Architect*. It will be seen that the artist has treated this everyday scene in a manner that is entirely original, and we must regret that we are unable to suggest the charming colouring of the original.

WAREHOUSE, BLACKFRIARS STREET, MANCHESTER.

THIS illustration is a reproduction of a drawing which was exhibited this year in the exhibition of the Royal Academy. The warehouse was erected a short time since for Messrs. BAERLEIN & Co., from the designs and under the superintendence of Mr. F. H. OLDHAM, F.R.I.B.A., 23 John Dalton Street, Manchester.

BUSINESS PREMISES, CALL LANE, LEEDS.

THE buildings represented in the illustration are being erected by the trustees of "The Charitable Uses Trust," to replace some dilapidated property which formerly stood on the site. They are planned to suit the requirements of the intended tenant, Mr. JOHNSON, who is a wholesale stationer and newsagent, and who will do a good deal of printing on the premises. The buildings occupy a somewhat prominent position at the corner of the junction of two much-used thoroughfares, and an attempt has been made to emphasise the situation by the provision of an angle turret with a domed covering. The contractors for the work are all local men, the architects being Messrs. CHORLEY & CONNOR, of 15 Park Row, Leeds.

## THE NEVILL MEMORIALS AT BRANCEPETH.

A PARTY of members of the Royal Archæological Institute visited Brancepeth Church after the meeting in Newcastle-on-Tyne, when the following paper was read by the Rev. H. J. Swallow:—

The colossal effigy of Robert Nevill, "the Peacock of the North," forms a conspicuous object in the chancel. This monument has been moved from the position it formerly occupied in the north transept. It has been slightly chipped in several places, but after the lapse of more than 550 years it remains the best preserved Nevill monument in existence.

The effigy is 7 feet 9 inches long, clothed in chain mail, with surcoat reaching to the knees. The head rests on two cushions, supported on six lions, with two small kneeling figures between them. The hands are elevated, the legs crossed. The feet rest on a lion. Beside one leg is a dragon, beside the other a muzzled dog, and the space between is covered with foliage. The sword is small, and dependent from a belt under the shield. The shield bears the Nevill saltier, and the label of cadency, by which the effigy can be identified without any manner of doubt. Robert Nevill died in 1319, during the life of his grandmother, Mary of Middleham, being her heir. There is no other Nevill to which this label could apply, and the whole character of the monument is agreeable to the age in which Robert Nevill lived. Stone effigies of cross-legged knights were sculptured down to the time of Edward II. The hauberk was worn by knights having estates, called in the Norman parlance *fiefs d'haubert*. The crossing of the legs is probably due to the whim of the sculptor, who adopted that disposition in order that he might the better exhibit the detail of the monument. Knights with their legs crossed are not necessarily crusaders, and Robert Nevill was certainly not a crusader, although he has often been described as such. The whole design of the monument was boldly conceived and carried out. It is a magnificent relic, and well deserves the reverent guardianship which it has so long received from successive generations of Brancepeth people, who have been content to pass away into the silence of the churchyard without carving their names upon, or otherwise disfiguring, this splendid monument of antiquity. Let us hope that a like spirit of intelligence may guide the hands of future generations.

The oak monument on the south side of the chancel has been less fortunate. It met with the fate of the prophet Isaiah. The name of the individual by whom it was sawn asunder has not yet come down to us, his memorial having perished for ever. Leland says that "in the paroch church of Saint Brandon, at Branspeth, be dyvors tumbes of the Nevills. In the quire is a high tumb of one of them, portured with his wife." The "high tumb" having been sawn asunder is now a low one. The upper part of the monument on which the effigies rest, and the plinth, with the bases of eighteen canopied niches, alone remain. The main body

of the tomb, with all its richly-carved figures, will never be seen again.

A view of the monument as it originally appeared has been preserved in the Herald's College, and a copy is given in Surtees' "History of Durham." By many writers it is held to be the monument of the great Ralph Nevill, first Earl of Westmoreland, and Margaret, his first wife. Stothard, however, describes it as that of the second earl, and Margaret, his second wife. Mr. John Hewitt, in his learned and exhaustive supplement to Stothard's work, is evidently perplexed over this monument. I cannot do better than append his remarks *in extenso*.

The remarkable points in these effigies are the collars which decorate the necks of the figures. The Lancaster badge of S.S. is now discarded, and we find that of York, the white rose in the sun, adopted.

In his body armour the knight is a good hundred years behind the fashion of his day. His suit is almost identical with that of the Black Prince. It is not easy to assign the cause of this resemblance. It may be attributed to the remoteness of his province from the metropolis, to the custom of wearing inherited armour, to the artists having copied some older monument, or to his having affixed a new head to a more ancient body. All these are probable causes, and all these may be very far distant from the truth.

In the head-piece of our knight, however, we have a novelty, the visored salade or sallet with its mentonnière. This kind of head defence approached so nearly to that of the ancient Greeks that the Italians contrived the ocularium after the classic model, and that head-piece now known to collectors as the Venetian salade is a *fac-simile* of the Greek casque, so familiar to us from the numerous representations of the armed head of Minerva. In fight the salade was brought down over the face so as to join the gorget. Subsequently a visor was added to it, the mentonnière retaining its old forms and duties. The Nevill effigy gives but a very imperfect idea of the visored sallet. It is evident that no artifice could bring that ocularium in useful proximity to the knight's eyes, and the mentonnière seems equally shorn of its fair proportions. Let us, however, respect the sculptor's motive, which was, no doubt, to bring into view as much as possible of the knight's countenance.

This head defence appears but very rarely in monumental sculptures. At Meriden, Warwickshire, is a good example figured in Bloxam's "Monumental Architecture." In brasses it is by no means of frequent occurrence. One of the best is that of Edmund Clare, Esq., in Stokesley Church, Norfolk, which is engraved in Cobman's works, Vol. I.

Lady Nevill wears the kirtle with tight mitten sleeves, made very low in front. The girdle, worn loosely, is attached by an ornament of suns similar to those of the collar; its chain probably suspends an aulmonière. The sideless surcoat is curious from its deep facing, most likely of fur. The mantle offers nothing unusual. The head-dress, which we must carefully disentangle from the tassels and corners of pillows, is a mitigated form of the steeplehead, and may be regarded as transitional between that and the pedimental coiffure.

The York badge of the white rose in the sunparhelion exhibited on the collars of these effigies was assumed by Edward IV. after the battle of Mortimer's Cross, in consequence of which victory he added the device of the sun to the white rose.

If, as Stothard asserts, this monument was erected to the second Earl after his death in 1484, it seems strange that the Yorkist badge, so fatal to the Nevills at the battle of Barnet, should appear such a prominent object on the necks of both effigies. If it be a late erection to the memory of the first Earl, and placed in the church at a time when the Nevills were in close fellowship with Edward IV., I can understand the introduction of the Yorkist badge. The body armour of the male figure is certainly more in keeping with the time of the first Earl than the second. Margaret, the second wife of the second Earl, was not buried at Brancepeth, but at Doncaster. Margaret, the first wife of the first Earl, was buried at Brancepeth.

The first Earl lies at Staindrop; but I have not been able to discover the burial-place of the second Earl. He was not a very remarkable character, and I see no sufficient reason for the association of his name with the Brancepeth monument. I have seen it stated that the canopied niches of this monument were filled with figures of the second Earl's children, but the author of this statement failed to remember that this Earl had only two children, and there are the remains of eighteen niches.

Leland says "there lyith in the chapelle on the south of the quier a Countess of Westmoreland, sister to Bouth, Archbishop of York. There lyith in that chapelle also the Lord Nevill, father of the Erle that now is (4th). This Lord Nevill dyed, his father the Erle yet lyving: whereupon the Erle tok much thought and dyed at Honreby Castle in Richmondshire, and ther is buried in the paroch church. The Erle of Westmerland that is now had an elder brother, and he lyith in a little tomb of marble by the high alter, on the south side; and at the feete of hym be buried four children of the Erles that now lyvith."

The high marble tomb that now lies under the tower (having been moved from the Jesus Chapel in 1876) is doubtless that of Matilda, daughter of Sir Roger Booth, of Barton, wife of the third Earl, and Ralph, her son. It is ornamented with the quatrefoils encircling plain shields. The shields on the south side have evidently been painted, and the Nevill saltier can be indistinctly traced. Lady Boyne, Rev. J. Lawson, and Mr. H. T. Peirson, were present during the removal of this monument. The skulls and other remains of two persons were discovered and reinterred.

Hutchinson speaks of a table monument in the Jesus Chapel without inscription, but exhibiting a shield with the Nevill arms dexter, sinister three boars' heads. Before the restoration of the church in 1863 an altar tomb without inscription is described by Rev. J. T. Fowler, and also by Mr. C. Hodgson Fowler, as standing in the centre of the chapel. A large marble slab is still recumbent under the organ.

Above the corbels of the nave roof will be noticed on the north side a bull, on the south an angel, each bearing a shield with the Nevill saltier. The bull's head of the Nevills also appears on the coloured panelling placed over the chancel arch, above the geometric tracery.

Bishop Dudley granted license, September 20, 1483, to Ralph Lord Nevill and Isabel his wife to found a chantry for one chaplain at the altar of our Saviour in the south part (*ex australi porte*) of the church of St. Brandon, Brancepeth, with an endowment in lands of ten pounds yearly. I have in my possession an exact copy of the original instrument.

### ENGINEERING SCHOOL, CAMBRIDGE.

THE new engineering school attached to the University of Cambridge has attracted a large amount of success. Professor Stuart was the originator of the school, and entirely at his own expense he fitted up some small workshops containing a few vices, some foot lathes for iron turning, some woodworkers' benches, and necessary tools. Skilled workmen were secured to teach the handicrafts, and the experiments rapidly became an assured success. Having demonstrated to the authorities of the University the practicability of his scheme, the Museums and Lecture-rooms Syndicate took the matter up, and since that time grants have been made from the University funds to enlarge the old workshops, to provide tools, &c. Application was also made for an assistant to the professor. This reasonable request was granted by the University, and resulted in the appointment of Mr. James Lyon, B.A., of Clare College, a graduate in mathematics, honours, and who possessed also the more important qualification, namely, being an engineer of some fifteen years' experience. The result of Mr. Lyon's appointment was to develop the scheme of the professor very rapidly. The workshops were found too small for the accommodation of the students, and the University authorities being again appealed to, new buildings were provided, and also additional appliances. There is now a foundry, smiths' and pattern-makers' shops, and a model engineering establishment in the very centre of the new museum buildings. The number of pupils continues to increase, and in the Lent term there were sixty-one. Professor Stuart reports that the average amount of work, both theoretical and practical, done continues to increase, and the work is of a higher standard than before. "I attribute," says Professor Stuart, "these results chiefly to the great ability, energy, and application with which Mr. Lyon, previously demonstrator and now superintendent, who now really manages the department, combines practical experience and theoretical knowledge in a manner rarely to be met with." Although the majority of the students are members of the University, others are admitted. Some of the members of the University have taken their degree, but the majority consist of those working to pass the University examination in mechanism and applied science. There is an excellent drawing office attached to the department, in which the students learn machine construction and designing, and they usually design some piece of mechanism which they are afterwards to make themselves in the shops. In his way one pupil has made a dynamo to absorb 6 horse-power, and this is now being used to light his father's house with electricity; another student has made a pair of steam-engines for a pleasure yacht; a third, a double-gear lathe; a fourth, a morticing machine; a fifth, a circular saw bench, and so on. There is no restriction as to what the pupil embarks on, save that it must be some real piece of work, not a plaything, and also each pupil has to go through a preliminary course which is prescribed by the department for those who are quite ignorant of engineers' tools and the uses to which they may be put. Among other things, philosophical instrument making is carried on to a large extent, electrical appliances are made and sent all over the world, while much work is executed for the different University laboratories, and the largest heliostat ever made has just been completed for Professor Living to enable him to examine the spectra of sun spots. With a view to making the workshops attractive and useful to intending emigrants, one shop is devoted to cabinet-making and general wood construction, and this is found of great use to young men who intend to follow the pursuit of land and estate agents.

A completely new line has been entered upon this summer, which, no doubt, will be of great service to many of the pupils, to say nothing of the benefit to the University. A large addition had to be made to the premises of one of the scientific departments by building another storey on the top of an existing museum, 120 feet long by 25 feet wide; but it was very undesirable to disturb the ceiling over this museum, which, being nailed to the main timbers

of the roof, rendered the subject a difficult one to deal with. Under these circumstances, the University authorities asked the advice of the mechanical department, which undertook to do the work. The result of the undertaking has been a complete success, for the ceiling has been cut free from the roof, and the latter, weighing about fifty tons, has been lifted bodily a height of 12 feet without removing a slate. The whole work undertaken was estimated to cost 3,000*l.*, and it is anticipated that a large saving will be effected on that estimate in consequence of the work having been carried out under the direction of the superintendent of the mechanical department.

### MOSCOW CATHEDRAL.

THE new cathedral at Moscow (says a correspondent of the *Times*) is one of the most remarkable churches in Europe. Not many cathedrals can boast of having been built in one lifetime, but there are Russians still living who saw the French army depart from Moscow, to commemorate which event the church of St. Saviour has been erected. In less than three months after the retreat of the foe a decree went forth from Alexander I. that a memorial temple should be built, and five years later the foundations were laid, but not on the present site. The emperor accepted plans which, had they been carried out, would have given to Russia the highest building in the world—namely, 770 feet, on the Sparrow hills, between the routes of the entrance and departure of Napoleon; but the undertaking for awhile collapsed, and the architect and building committee, after expending or misappropriating in ten years upwards of four millions of roubles, were banished, and their estates confiscated. The Emperor Nicholas adopted new plans, and chose the present site, which has cost, with embankment, terrace, &c., upwards of 180,000*l.*, and where at the outset a nunnery had to be removed and 70,000 cubic feet of earth to be displaced before, on July 27, 1838, the laying of the foundations was commenced. The building continued slowly to rise for twenty years, and in 1858 the scaffolding was removed, this latter item alone having cost 277,000 roubles, or upwards of 40,000*l.* (reckoning the rouble, that is, at three shillings, as throughout this letter). A quarter of a century more has been expended on fittings and decoration. The style is ancient Russian, or rather Græco-Byzantine, the most striking feature of which, to a Western eye, on the exterior is the five copper cupolas, for the gilding of which were required 900 pounds of gold, their total cost being upwards of 170,000*l.* The domes are surmounted by crosses—the centre one, nearly 30 feet high, standing 340 feet from the ground. The building covers an area of 73,000 square feet. The bells, as usual in Russia, are of ponderous weight. The largest, or "holy-day" bell, weighs 26 tons, or half as much again as "Great Paul." Even the second, or "Sunday" bell, is within a ton's weight of our bantling; while the smallest of the "every-day" bells descends to about 30 pounds. The cost of the peal was upwards of 13,000*l.*

The foundations of the church are of Finnish granite, and the whole edifice is faced with marble, the doors being of bronze ornamented with Biblical subjects, and lined with oak. The principal entrance measures 30 feet high by 18 feet broad, and the two doors weigh 13 tons, the total cost of all the doors being 62,000*l.* Thus, it will be allowed that many of the features of St. Saviour's are produced on a magnificent scale, though one familiar with the spire of St. Stephen's, Vienna, or that of Salisbury, the west front of York Minster, or that of Amiens, might hesitate to pronounce the effect of the exterior of St. Saviour's beautiful. As to the interior, there can be, I think, little difference of opinion. I have seen most of the celebrated cathedrals in Europe (with the exception of those of Spain), but in its way I know of nothing so exquisite as the interior of St. Saviour's at Moscow. The building is erected in the form of a Greek cross, three of the broad ends of which form corridors, lower and upper, surrounding three sides of, and open to, the central square or temple proper, while the fourth end is occupied by the altar and its appurtenances. The upper corridor reminded me of the galleries in Santa Sophia at Constantinople. The walls are adorned with frescoes illustrating principal events in the history of the Russian Church, one of which, I remember, elicited during my visit a characteristic remark from an American tourist, whom, with his daughters, I had invited to join my party. The painting represented an ecclesiastic commencing to dig the foundation of the Kief Monastery, in the eleventh century, before which my Transatlantic cousin pulled up and exclaimed, "Halloa! turning the first sod for a new railway." The walls of the lower corridor or "procession gallery" are adorned with paintings commemorative of the battles of 1812.

But it is when one stands in the temple proper, and looks above and around that the gorgeousness of the building is so striking. The floor of this part is 220 feet square, the length of the cross either way 270 feet, and the height from the ground to the cupola measures 230 feet. The floor is of marble, and the walls are lined with exquisite varieties of the same material. It was intended at first to use only Russian marble, but some amount of Italian was subsequently found to be indispensable.

The total cost of all the marble in the building exceeded 300,000*l.* Lifting one's eyes the galleries are seen to contain thirty-six windows, and the cupola sixteen, all of which are double, with frames of bronze. Round the cupola is one row of 640 candelabras, placed there at a cost of 27,000*l.*, with a second row of 600, costing an additional 12,000*l.* There are four lustres weighing four tons each, and the total number of candles to be lighted throughout the building is upwards of 3,000. At the top of the cupola is a painting by Professor Markoff that will freely shock the principles of Westerns, who object to the use of pictures in worship. It represents in colossal proportions the first person of the Blessed Trinity as an old man with the infant Jesus. The height of the figure is 49 feet, the length of the face 7 feet, and the height of the infant 21 feet. Also, below the cupola are a number of figures of apostles and fathers each 21 feet high. Great expense has of course been lavished on the eastern end of the church. The cost of materials and workmanship for the altar-space, apart from the *icons* or sacred pictures, amounted to 36,000*l.* In this part of the church are some of its most remarkable paintings, most, if not all, by Russian artists. They are too numerous to particularise. I remarked, however, a striking picture of Sergius blessing Demetrius of the Don. I see from my notes that the *Last Supper*, by Semigratzky, and eleven pictures by Verestchagin attracted my attention. The structure of the altar-screen is a departure from the traditional Russian type, for instead of a tall, ugly blank partition, half or two-thirds of the height of the church, hiding the eastern end, the screen of St. Saviour's is low and elegant, and throws open, except for a few feet above the floor, the whole of the sanctuary. But a more marked and, as some would think, unorthodox departure from the customs of the Russian Church is the construction of the altars. I am under the impression, gathered, I think, from the work of the learned Dr. Neale on the Eastern Church, that the "holy table" in the Russian Church should be always of wood; whereas in St. Saviour's I saw two at least constructed of blocks of polished marble, the semblance of a table being given to each by a movable inch board of cypress wood laid on the top. Much of the ornamentation of the sanctuary and its furniture was exceedingly beautiful, notably some enamelled candelabra by Klebnikoff; but perhaps I have sufficiently described this princely cathedral, erected at a cost of two and a quarter million pounds sterling, said to be capable of accommodating 10,000 worshippers, and which from its first conception has been built, as I have said, in a single lifetime.

### COMEDY THEATRE, MANCHESTER.

THE new theatre, which is to be called the Comedy, now erecting in Manchester for Mr. Edward Garcia, is situated in Peter Street, nearly opposite the Theatre Royal. The principal façade, 105 feet in length, and main entrances will be towards Peter Street, the gallery and stage entrances being in Bootle Street. The building is arranged and divided longitudinally into three parts. The front portion contains the entrances and exits, the foyer, retiring and refreshment rooms; the centre portion is occupied by the auditorium; and the back part is devoted to the stage and its appliances. The adjacent property on the western boundary has been secured by Mr. Garcia, in which will be placed the dressing-rooms, property-rooms, and the paint-room, all of which will be approached directly from the street, but conveniently connected with the stage.

The means of ingress and egress have had the most careful consideration of the architect, and have been arranged in consultation with the city surveyor. All public staircases are 5 feet wide, 12 inches tread, and 6½ inches rise; they are constructed of solid concrete resting on iron supports, and without "winders" or other dangerous expedients. Every part of the auditorium is provided with an exit staircase at the opposite side of the house from the entrance staircase, and leading direct into Peter Street. An interesting feature in the planning of this theatre is the placing of the pit below the ground level, and thus enabling the occupants of the dress circle to enter the foyer on a level with the entrance, which is raised one step above the level of Peter Street. All parts of the house are provided with cloak rooms and the necessary conveniences. The seating accommodation will be as near as possible as follows:—Stalls, 70 seats; pit, 667; dress circle, 200; upper circle, 264; gallery, 710; making a total of 1,920 seats, which with standing accommodation would realise an audience capacity of about 2,500 persons.

A new departure has been made in the style and design of the building, the architect having decided to adopt that phase of Gothic architecture only to be found in Venice, or in other words, the theatre is being carried out in "Venetian Gothic." The façade is faced with red brick, and strings, corbellings, oversails, and pointed arches are executed in terra-cotta; the labels, columns, balcony, &c., are executed in Halifax stone, which forms a pleasing contrast to the red brick facing. The interior is carried out in keeping with the style of the exterior; the circle tier will have a handsome front of fibrous plaster, consisting of a small arcading

filled in with gold and conventional flower decoration in colour; the other tiers are simpler in character, but the upper circle tier will have at intervals shields emblazoned with the arms of Lancashire corporate towns. The proscenium will be finished with a deeply moulded architrave, forming a sort of frame to the stage pictures. Above the proscenium will be a recessed arcade formed by three Gothic-headed panels, columns, and archivolts. In the centre compartment will be a seated figure typical of the Drama, those on the right and left being filled respectively with figures, symbolic of Music and Painting. These figures will be flat and decorative in character, and in the style of the proscenium frieze executed for the Prince's Theatre, by Mr. H. Stacy Marks, R.A. The proprietor has determined to furnish and appoint the theatre in the best style, and in keeping with the general character of the building, and in harmony with the scheme of colour decoration. The stage is being laid with due attention to simple but efficient working, and will accommodate any kind of production that may come within the manager's programme. The theatre will be lighted both by the electric light and gas jets, all thoroughly under control, the stage lighting being kept entirely distinct from the lighting of the front of the house. The building is now rapidly approaching completion, and will soon be handed over to the decorative artists, who will finish their work in time for a Christmas opening.

The building has been designed, the plans prepared by, and the whole of the works, including the decorations, are being carried out under the immediate superintendence of the architect, Mr. Alfred Darbyshire, F.R.I.B.A., who for many years was associated with Mr. Calvert and Mr. Browne in the decorations and alterations at the Prince's Theatre, Manchester, and more recently with Mr. Irving, at the Lyceum, London. The contractors for the entire work are Messrs. R. Neill & Sons, the Government contractors, of Manchester.

### THE TOWN OF BUCKINGHAM.\*

THE town of Buckingham is doubtless one of great antiquity. Historians tell us that about A.D. 44 a Roman general under the Emperor Claudius surprised the Britons on the banks of the river Ouse at or near Buckingham; and, further, on the first spreading of Christianity, in the Saxon times, it became remarkable as the burying-place of St. Rumbold, who was born at King's Sutton, November 1, 626, and where he also died, appointing his body to rest there the first year, the next two years at Brackley, and at Buckingham for ever after—where, as the historian and antiquary Browne Willis informs us in his interesting history of the county, a shrine was made for him in the parish church, to which great resort was made by pilgrims, and many miracles are reported to have been wrought by him there.

The same historian tells us that this town is mentioned in the reign of King Alfred on his division of the kingdom into shires, when he fixed on this place as the capital of his newly-erected county, and that his son King Edward the Elder took up his quarters here A.D. 918, caused two forts to be built and garrisoned on each side the river Ouse, and then, advancing towards the Danes, struck such terror into them that they were glad to make peace. Subsequently to the survey of Domesday Book, in which mention is made of the town, few records are to be found. Tradition, however, preserves some memories until recent date of a castle, and adds, besides, "a local habitation and a name," for we have Castle House, Castle Street, Castle Mills, Castle Farm, Castle Fields, and Castle Hill; yet no written record is extant of the building of a castle, nor, as far as I can ascertain, do any traces of a foundation remain, although we read that in A.D. 1484 Richard III. made a grant to John Grey, of Wilton, of certain monies for the food of the king's hawks, secured upon the castle and manor of Buckingham. My learned predecessor, the Rev. H. Roundell, tells us that the bailiff and burgesses of the Corporation were summoned in King Edward III.'s time to send three representatives to the Council of Trade held at Westminster by that Prince; and in Henry VII.'s time the county weights and measures were ordered by Act of Parliament to be kept here. He informs us also that the gaol delivery of felons and all county business was transacted here until (as it was supposed), by the influence of Chief Justice Baldwin, a native of Aylesbury, the assizes were removed to that town during the reign of Henry VIII.

In 1553 Queen Mary granted a charter of incorporation to this borough; a second charter, with increased privileges, was granted by Charles II., A.D. 1684, under the authority of which the government of the borough was conducted until the new Corporation Act came into force in 1835. The year 1568 is memorable in the annals of our town from the fact that on the 25th day of August (as we learn from a mem. in the Corporation book of that date) "the high and mighty Princess, Queen Elizabeth, came in progresse to the Burrow of Buckingham, and at the utmost part of the limits of the liberties of the said Burrow . . . the Bayliff and the 12 principal Burgesses of the said Burrow made their most

\* A paper by the Rev. F. G. Kiddle, read at the meeting of the Bucks Architectural and Archæological Society.

humble submission and received Her Grace. Whereupon Her Highness did admit the said Bayliff to be her Chamberlain within the said Burrow by delivering him one white wand. And to pay proper honour to the said Burrow Her Majesty had, in a most triumphant manner, her sword royal and maces borne, and trumpets blowne, until she came to the mansion house of the Rector or Prebendary of the said Burrow, where Her Highness rested dinner-time; and after dinner ended Her Grace proceeded forward to the town of Bicester," &c.

During the civil wars of the seventeenth century Buckingham, unlike all the other towns in the county, refused to espouse the side of Parliament, and from a document in the Bodleian Library we learn that "this corporation preserved its integrity and was eminently serviceable in assisting the University and City of Oxford, which were the chief support and assistance of King Charles I."

Time will not allow us to quote from the interesting records which are preserved to us of this time, and we pass on to mention the great fire of 1725. In a handbill circulated at the time it was stated that 138 dwelling-houses and a great many barns and stables and other outbuildings were totally destroyed, and that the loss over and above all money recovered from any insurance office whatsoever amounted to 32,682*l.* 13*s.* 6*d.* Unhappily for the appearance of the town, the corporation did not apply for an Act of Parliament whereby the rebuilding of the houses would be regulated—a step strongly urged by Browne Willis, of Whaddon Hall, to whom we have already referred as author of the valuable "History of Buckingham" which bears his name. The mention of this name induces me to quote once again Roundell's words. Mr. Willis, he says, "must be reckoned among the best friends Buckingham ever had. By his exertions a large sum of money, of which he contributed the major part himself, was expended on the repair of the church tower, the spire of which had fallen down on February 7, 1699. He originated the plan for building the present gaol, of which he witnessed the completion by Lord Cobham. He procured the restoration of the assizes to Buckingham, strenuously resisted an intended removal of them to Aylesbury, and persuaded both the Bishop of Lincoln and the Archdeacon of Buckingham to hold their visitations here. Indeed, he devoted his best energies through fully half a century to restore to Buckingham its ancient honours." With this quotation I must conclude this brief and imperfect sketch of the town and proceed to speak of three special points of interest—the Church, the Latin School, and Castle House.

The old parish church of the town stood in the old churchyard, the entire length of the building being 163 feet, consisting of chancel, nave, and side aisles, with two large transepts, and a square tower, supporting a spire of wood covered with lead. If the engravings extant of this church are correctly drawn the date of tower, spire, and nave may be attributed to the thirteenth century. The chancel was built by John Ruding, Archdeacon of Lincoln, upon his appointment to the Prebend of Buckingham in 1471, of which date also we have preserved to us a MS. Latin Bible presented to the church by him, and which through private liberality has once again come into our possession. On February 7, 1699, the tall wooden spire was blown down in a gale of wind, but no material damage was done to the rest of the building. In 1753 the tower was raised in height about 24 feet, but the increased weight of masonry proved too great for the old piers which supported it, and on March 26, 1776, the fall of the tower took place, only a few minutes after the ringers had left it. At the request of the town, Earl Verney gave a site on Castle Hill for a new church, and upon the payment of 4,000*l.* raised upon the security of the poor rates, and the assignment of the old materials of the former church, Earl Temple undertook to build the present edifice, the first stone whereof was laid November 25, 1777, and the building consecrated by the Bishop of Lincoln December 6, 1781. But from the present appearance of the church we should with difficulty picture to ourselves the building of which I am speaking. My immediate predecessor, the Rev. W. F. Norris, now rector of Witney, says when he succeeded to the vicarage in 1862 he found the church in a dilapidated condition. There were sixteen large cracks in the walls, indicating the faulty construction of the windows and scamped foundations, and that the church was altogether in so dilapidated a condition as to be unfit for its purpose. Sir G. G. Scott designed a method of support by buttresses and a general remodelling of the exterior and interior, and, after a period of twenty years, the work has just been concluded, at a cost of about 11,000*l.*, exclusive of the handsome chancel, which was the gift of the present Duke of Buckingham, and built at a cost of over 2,300*l.*, the foundation of which was laid by the late lamented Duchess of Buckingham, July 1865.

The Royal Latin school, which is without doubt the oldest school in the town, was erected by Matthew Stratton, Archdeacon of Buckingham, 1260, who dedicated its chapel to Thomas à Becket, probably in memory of that prelate's visit to Buckingham as Chancellor, 1169. After the lapse of 200 years the building became dilapidated, and the chapel was partially rebuilt by Archdeacon Rudy between 1470 and 1480. After its restoration the building was used as a chantry chapel till 1546, when it was presumably used for the grammar school founded here by the Royal

Commission at that date. In the lapse of years this chapel became for the second time dilapidated. The roof fell in, and the ground floor was dug up and used as a garden. In 1776 a new roof, constructed principally from the timbers of the old church, was placed upon the building by Col. Temple, and the chapel used for divine service during the erection of the present church. Since that time it has again been used for educational purposes. It is an interesting building and will well repay you for a visit if you care to see it.

It is only necessary for me to mention that Castle House was the headquarters of King Charles I. during his stay in this borough, A.D. 1644. Here it was that the Lady Richardson, mistress of the house, received and paid homage to her sovereign and gave him a hearty welcome.

## ENGLISH SCHOOLS.

THE reports of some of Her Majesty's Inspectors of Schools for 1883 have been printed. The following extracts relate to the condition of the school premises:—

### *Durham District.*

Mr. A. E. Bernays writes:—With reference to school accommodation I am able to report most favourably, and, except in one or two cases, there is now ample provision for the district. Since 1879 twenty-three new schools have been opened, *i.e.*, eighteen Board, two Colliery, and three Roman Catholic, while additional premises have been built or are in course of construction at eleven Church of England schools, eight British and Colliery schools, seven Roman Catholic schools, four Board schools, one Wesleyan school. At the same time only four denominational schools have been discontinued, and thus far, therefore, the Board system has not in any way been detrimental to voluntary effort. In fact it has had a stimulating effect in several instances, and those most opposed to the Act of 1870 are fast coming to see that their dreaded foe is after all but an honourable rival. The proposed infants' school in Durham has not yet been commenced, but I believe there will now be no further delay in the matter.

As regards premises, furniture, and apparatus, a great improvement has been effected; and I think I may safely say that, as far as circumstances permit, there is not a badly-ventilated school in my district, though we have not yet reached the ideal of 540 cubic feet per child, as recommended by a Munich professor. I am also engaged in combating the evil of over-crowded class-rooms, which are by no means uncommon, even when the requirements of the Department are fulfilled in the aggregate amount of space and area. In every school, too, there is either a proper lavatory or two or three washhand basins; and I am glad to observe that there are now hardly any galleries for infants which are not fitted with backs to the seats. I much wish, however, that managers would recognise the need of providing chairs or high stools for the teachers, and an adequate supply of hat-pegs for the children. I also hope to see a larger number of pictures both in the senior and junior departments. Of course those of real artistic merit, such as Mr. Ruskin would have, are beyond the means of most schools; but the love of what is beautiful or pathetic can be inculcated without lavish expenditure in these days of cheap engravings and coloured prints.

The offices, though better than they were, are not yet what they should be, and I have still considerable difficulty in getting either managers or teachers to see that they are properly kept; but, where warnings are unheeded, the reduction or loss of the merit grant will doubtless have the desired effect. Apart from the sanitary aspect of the question, the state of these places is undeniably of the utmost importance in regard to habits of cleanliness and decency; and I would, therefore, recommend that two or three of the elder children should act as monitors, and be made responsible for each playground.

### *Plymouth District.*

Mr. H. Cowie writes:—The school supply of the district may be looked on as nearly complete, except as regards Plymouth. According to the calculation of the Plymouth School Board, 1,286 places have to be supplied. This deficiency the Board proposes to make good by enlarging the existing schools in Mount Street and Castle Street, and by building a new school of four departments in Cattedown Road, at the east end of the town. In addition, they also propose at some future time to build a school of three or four departments at the west end. These schools will consist of separate departments for boys and girls over nine, mixed between seven and nine, and infants. This organisation has, I believe, been adopted at Liverpool. Outside Plymouth very few places call for further school supply. A new school is required at Horrbridge, the existing building being in bad repair, and incapable of improvement. At Shaugh Prior there is no school under inspection, although the parish has had a School Board since 1874. The Board has, by a policy of masterly inactivity, contrived to stave off the question of providing efficient schools for nine years, but at last even your Lordships' patience has been exhausted, and a final

notice has been given, which seems to have aroused the Board and the parishioners to the inevitable consequences of their neglect. In a few months I hope to have schools at Shaugh village and Le Moor Clay Works placed under inspection.

Since my last report (1879) several new schools have been added in the Launceston Union, Lezant Board, Broadwoodwider Board (2), and St. Stephen's by Launceston; in Camelford Union, Boscastle Girls' Board and Michaelstow Board. In East Stonehouse new schools for girls and infants have been built during the past year in place of an infant school held in hired premises in East Street. The accommodation at Stonehouse N. and St. Paul's C.E. has been increased. At Launceston both the Board and National schools have been enlarged and separate infant departments formed.

The larger School Boards as a rule do their work well; the buildings are spacious, well arranged, and kept in good repair, the supply of books and apparatus ample, the teachers are well paid, and the staff sufficient. Many of the small country boards, on the other hand, seem to consider that their paramount duty is to keep the school rate at the lowest possible figure. The buildings, sometimes shamefully scamped by some local "jerry-builder," go from bad to worse; the teacher's salary is cut down to the lowest sum that some person who has failed elsewhere is willing to accept; the staff is kept at the minimum, and the inspector's requirements as regards staff, books, maps, &c., are resisted or evaded up to the last moment, and then complied with only to escape the threatened fine. When we consider that farmers as a class have no interest in or experience of the management of schools, that they commonly regard popular education as injurious to their interests, and that they have to bear a new burden in the school rate for an object with which they have no sympathy, we cannot wonder that the results of committing the charge of education to this class should prove unsatisfactory.

#### *Manchester District.*

Mr. H. E. Oakley writes:—There is accommodation for about 117,000 children, which is more than one-sixth of the population. The statement of gross accommodation is, however, misleading when it deals with a large area, for there may be on the whole more than sufficient provision for all the children, and yet a deficiency here and there. Thus, in Manchester at least, 15,000 people have within a few years moved from the centre of the city to the suburbs, in consequence of the improvements which have uprooted many squalid streets and cellars, with the natural result that one at least of some large schools is rendered practically unnecessary, whilst on the other hand additional accommodation in the outskirts of the town is required. In a report made ten years ago I begged for greater attention to what I think a very important point, the adornment of the schoolroom by flowers, pictures, casts, &c. It is strange that some people think a schoolroom quite good enough if periodically whitewashed and furnished with necessary school appliances. In many parts of a densely-crowded large town the children never see anything beyond four or five hideous streets surrounding their altogether unlovely dwellings. Is it not quite clear that there is a direct and powerful educational advantage in showing them beautiful things in the only place possible—their school? Where some pains have been taken to develop the love of beauty, it is touching to see the children's delight. The committee of the Manchester Art Museum intend to offer to managers of elementary schools small loan collections of good pictures, casts, and pottery, including coloured pictures of common flowers, ferns, trees, birds, and of such pretty places as town children may see on the rare occasion of a country trip. I wish everyone would read an excellent pamphlet by Mr. Horsfall, the originator of the scheme, entitled "Art in large towns," which forcibly shows the importance from many points of view of encouraging among the working classes an interest in beauty and in art, still regarded by many as a plaything for idle people. I have not space to dwell further on this good movement, but I heartily wish the committee every success, and shall be very glad to see their promised loans.

#### *Northumberland District.*

Mr. D. P. Pennethorne writes:—The annual average attendance does not show the state of the schools on some days, as a glance at the highest weekly average will show. It will then be seen how crowded some schools are at certain periods of the year; such schools should be enlarged. An infant school should have a large area to admit of marching and other exercises. It is true that infants take up but little space, so that eight square feet means more for them than for older children; but in passing a school in respect of premises regard should be had to the area in front of the gallery, so that rooms fit only for infants' class-rooms should not be passed as infants' schools.

#### *Leeds District.*

Mr. A. G. Legard writes:—When the new buildings, which are already in hand or projected, are completed there will be forty-two permanent schools within the borough with accommodation for about 32,000 children; and if the extra schools be taken into

account, the total accommodation in Board schools will be sufficient for about 33,700 children. The number of voluntary schools in Leeds remains much the same as it was ten years ago, nor is it likely to increase. There are at present fifty-four of these schools with accommodation for about 16,700. Accordingly it may roughly be said that the Board provides school places for two-thirds of those who require it, while voluntary managers supply places for the remaining one-third.

It must be admitted on all sides that considerable energy has been shown by each of our Boards in succession in grappling thus successfully with the first problem that awaited solution after the passing of the Act of 1870. The cost has certainly been great, as is apparent when it is noticed that the education rate has risen from 3*d.* to 11*d.*; but our ratepayers may comfort themselves by the assurance that the newer Board schools are not only much better, but, as a rule, much cheaper than the older ones.

The Ellerby Lane Board School, for example, opened in 1877, cost per child 12*l.* 1*s.* 3*d.*, exclusive of the site; whereas the Dewsbury Road Board School, opened in June 1883, cost on the same basis of reckoning 8*l.* 7*s.* 10*d.* per child. The cost of building has no doubt decreased within these six years, and it has also been the policy of the Board latterly to build schools of four departments where possible—a policy which has promoted efficiency and diminished expense. In the newer schools class-room accommodation is provided for three-fifths instead of two-fifths of the total number of children, and the main room can also be divided into two by a movable partition of glass. On the other hand, in some of the older of the Board schools (Sweet Street, for example) the class-rooms are small and inconvenient. The policy of increasing the number of class-rooms almost necessitates the employment of additional adult teachers, and it is interesting to notice that in 128 departments no less than 247 certificated teachers are employed, and 124 adult teachers not certificated; consequently there is one certificated teacher to 101 children, and one adult teacher to 67 children. In the Church schools there is one certificated teacher to 101 children, in the Wesleyan and British one to 130, in the Roman Catholic schools one to 95. This proportion is not satisfactory, but a further advance in the same direction is most desirable.

#### *City of London.*

The Rev. T. W. Sharpe writes:—It is most desirable that expensive groups of buildings for the accommodation of large numbers should not be built within the boundary of the City, the danger of crossing crowded thoroughfares, the great cost of any site even without a playground, the confined space, and the difficulty of obtaining a quiet locality, present obstacles to the building any large schools within the boundaries; it would, therefore, be more healthy for the children to flow outwards from the City into schools outside the boundaries, and less expensive for the ratepayers. The outskirts of the City, in which most of the children live, could be taken into connection with Westminster on the west, Finsbury on the north, and Tower Hamlets on the east. The City district really requires a certain number of junior schools for children between the ages of three and eight or nine, placed between the great arteries of traffic, so that no young child should be required to cross a dangerous thoroughfare.

I have divided the buildings of the inspected schools into temporary, fair, and good. By temporary I mean buildings temporarily rented pending the acquisition of permanent premises, and by fair, buildings which do not possess a sufficient amount of classroom accommodation, but are otherwise satisfactory. Two only belong to the former category—St. Bride's Infant and the 2nd City of London National, which have been held on the lowest, the second, and third floors of a building of which the first floor was used as a workshop. A sum of 10,000*l.* has been lying in Chancery for the building of one of these schools, and a sufficient sum is provided for the other, but the managers have failed for several years to secure a suitable site. All the other buildings can be regarded only as fair, except the Graystoke Place Board School, which presents the usual excellent features of a Board school, Aldersgate Ward, Lady Holles' Charity, and Bishopsgate Ward Girls' School, *i.e.*, there are really only four good school buildings in the City.

The ward schools present some interesting features; Billingsgate Ward school is held in a house of some pretension, built by a merchant shortly after the great fire; the rooms are sufficiently spacious, but the situation between two lanes, one of which is devoted to the wholesale dealers in oranges and other fruit, and the other to a trade in salt fish, is never very savoury, and is at times unwholesome for young children; but it is on the whole better for the poor children of the neighbourhood to have this place of refuge close to their homes than to have to fight their way through Billingsgate or Tower Street to a more commodious school.

Aldgate Ward school is another harbour of refuge; delightfully quiet rooms sheltered by a courtyard from the noise of the great thoroughfares. The estimation in which the education of girls was formerly held is shown by the comparative size of the boys' and girls' schools, the boys' school accommodates 100 scholars, the girls' school about forty.

*Southwark District.*

Mr. S. N. Stokes writes :—The formation of the School Board for London with power to take sites and money to build upon them was speedily followed by increased supply of school accommodation, and the least skilfully designed of the new buildings excelled in construction and equipment, in elevation and extent, the best of the older institutions. Compared with such dens as the Bermondsey Railway Arch or the Lancaster Street Manger, even such Board schools as Great Hunter Street or Neckinger Road might well be called palaces. Still, fine as the first Board schools appeared by contrast with the hovels previously occupied as schools, experience has shown, as some experts foresaw, that for purposes of instruction and discipline the earliest plans were faulty in important points. The later Board schools exhibit material improvements in plan, and it may not be useless to examine the difference between the two groups so far as to point out features to be avoided in planning schools :—

Schoolrooms should not be passages to other schoolrooms, but every schoolroom should be reached from a corridor.

Schoolrooms should not be designed for a smaller number of scholars than will occupy an adult teacher.

Sufficient cloak-rooms, with doors and fastenings, should be provided, so that articles of clothing may not hang unprotected in passages.

The offices should be external to the schools, not opening on to the staircase or having any interior communication with the schoolrooms, and they should be of adequate extent.

Water or air, heated by a single furnace, cannot be relied on to warm several rooms on different floors.

There should be approaches to the schools from several sides through streets sufficiently wide and quiet.

In the size and arrangement and fittings of offices even the later Board schools leave something to be desired. The fact is, the problem was new. Hundreds of children, many of them too young to attend to themselves, and more of them from homes destitute of conveniences essential to habits of decency and cleanliness, had not before been gathered together into one spot. Hence offices, which as supplementary to home care would suffice for occasional use, become dirty and noisome in the large Board school. The new race of teachers are perhaps less motherly than their predecessors in attention to the little ones, and one male school-keeper cannot cope with the carelessness of 1,000 or 1,500 children—two-thirds of them girls or infants—even if it were possible and proper for him to be always amongst them. The matter has important bearings upon good habits and morals.

*North London District.*

Mr. T. W. Danby writes :—I undertook the charge of this district about the time of my last general report, and found the school supply already settled. In the rural parts of the district not many changes have been made or found necessary since; but in the suburbs of London, in Hornsey, Tottenham, Edmonton, the population grows so rapidly and is so migratory that the questions of supplying school accommodation for the people, and of making the people avail themselves of the accommodation supplied, are only tending towards a settlement. In the extra-suburban area there can be but few children who are not within reasonable distance from some recognised school in which there is room for them.

In the erection and enlargement of schools adequate care and thought are not bestowed on such points as light, warmth, ventilation, arrangement of desks and galleries, position of offices, &c. These are not trivialities, for on them largely depends the efficiency of schools. It, however, becomes obvious to one who visits scores and hundreds of schoolrooms, either that architects and builders consider these things beneath professional notice or that they are ignorant of the rudimentary scientific laws which regulate them. Insufficient warmth, defective ventilation, inconvenient, uncomfortable desks and galleries, introduce unnecessary friction into the working of educational machinery, and make themselves felt in unexpected insufficiency of instruction. Children, especially young ones, become torpid when the schoolroom temperature is too low; and neither they nor their teachers can long work with diligence in an atmosphere charged with the waste products of respiration. If children have to sit in strained attitudes because their writing desks are inconvenient, or because daylight is admitted in a wrong direction, or if they have to maintain a precarious balance on loose forms, with no rest for backs or support for feet, much energy is abstracted from their work, and lassitude and inattention speedily supervene.

Many schoolrooms are so furnished with convertible desks, movable platforms, and the like, that they can be used for lectures and meetings. It is an advantage that the usefulness of the premises should be as great and varied as possible, but it would be well if managers always remembered that the primary use of a schoolroom is for elementary instruction, and that in furnishing such a room the lecture or meeting should not be kept so prominently in view as the school.

**The Duke of Rutland** on Wednesday opened a public recreation ground, of eighteen acres in extent, at the town of Bakewell.

## THE NEWCASTLE LIBRARY.

THE public library in Newcastle-on-Tyne is one of the best in the provinces, and it has the advantage of an excellent catalogue, which is sold to the public for a small sum. The following list will give a notion of the class of books which relate to fine arts, topography, and archæology:—Bewick's works; Bourne's "History of Newcastle;" Bruce's "Lapidarium Septentrionale, Description de l'Égypte, ou Recueil des Observations et des Recherches qui ont été faites en Égypte pendant l'Expédition de l'Armée française, Publié par les ordres de S.M. l'Empereur Napoléon le Grand"—the Duke of Hamilton's copy, specially bound for Beckford by Wright; Domesday Book—the copy of the late Sir Henry Ellis, librarian of the British Museum, with extra pages and MS. notes; Dugdale's "Monasticon;" Grey's "Chorographia, or a Survey of Newcastle"—first edition, Newcastle; Hodgson's "History of Northumberland," a fine copy bound by Riviere; Jones's Alhambra—large paper from the Hamilton Palace collection; McLauchlan's "Eastern Branch of the Watling Street," and McLauchlan's "Roman Wall," privately printed by the Duke of Northumberland; Roberts's "Holy Land, Egypt, and Nubia"—one of the ten copies specially prefaced and each plate hand-coloured by the artist; Schoolcraft's "North American Indians," published by the American Government, and now very scarce in a complete form; Stothard's "Monumental Effigies," Surtees' "History of Durham," and Raine's "North Durham;" Akerman's "Remains of Pagan Saxondom," Allen's "History of the County of York," catalogue of "British Antiquities at Alnwick Castle," edited by Bruce; and "Catalogue of Egyptian Antiquities at Alnwick Castle," edited by Birch; "Archæological Survey of Western India," "Bartolozzi and his Works," Brand's "History and Antiquities of Newcastle," Bruce's "Roman Wall," folio, 1867, only twenty-five copies of which were printed in that particular form for public use; Fergusson and Burgess's "Cave Temples of India," Grose's "Antiquities of England and Wales, Scotland, and Ireland," all large paper; Grüner's "Ornamental Art," "Hogarth's Works," fine edition; Lyson's "Magna Britannica," Penley's "English School of Painting in Water-Colour," "A Collection of Works relating to the River Tyne, from A.D. 1603 to A.D. 1850;" Smith's "British Mezzotint Portraits," Smith's "Catalogue Raisonné," Turner's "Liber Studiorum," Viollet le Duc's "Dictionnaire de l'Architecture française," and "Dictionnaire du Mobilier français."

## SWISS WOOD-CARVING.

AMERICANS, who are always seeking after some new thing, especially if they can turn thereby an honest penny, have lately, writes a correspondent of the *Times*, begun to practise the art of carving in wood, and, rather to the annoyance of zealous Swiss patriots, several wood-carvers of the Bernese Oberland have been persuaded to emigrate to the United States, where they earn, it is said, as much as eight dollars a day—more than they can earn at home in a week. This, turned into francs, sounds a good deal, and is, indeed, an undeniably high wage, eight dollars a day being nearly 10*l.* a week, only a little less than the salary of the President of the Confederation. For all that, the *Berner Post* and other papers of the district are strongly of opinion that the wood-carvers would do much better to stay at home. They say :—"Do not be so selfish as to follow the example of the horologists of the Jura, and establish in America a new trade which will compete with one of our most important local industries. In the United States you will be far away from your native mountains, from the scenes which suggest and the objects which inspire. The only works of art you will see are statues of Washington and Lafayette, and though you may earn more money you will not be half as happy as you are at Brienz and Meyringen and Interlaken. Stay at home, and instead of going to America let the Americans come to you and buy your chalets, your bears, and your chamois, in the land where they are made."

How far these persuasions will be effective remains to be seen, but it is greatly to be feared that the inducement of 40 frs. a day may prove more potent. On the other hand, the attachment of the Swiss to their homes has passed into a proverb, and although some of the watchmakers of the Jura have gone to America, the dearest of them, those who live in the valley of Lake Joux, resolutely refuse to leave their native mountains and abandon their traditional habits for all the inducements that foreign capital can offer. So Americans, when they want fine or complicated watches are still obliged to resort to Switzerland, and an enterprising American horologist, who lately invented a new and elaborate timekeeper, not being able to find in his own country the highly-skilled labour which its production upon a large scale requires, has found it expedient to settle in the Confederation, and manufacture there the wares which he sells in the States.

Swiss wood-carving is a much younger industry than Swiss watchmaking. It was introduced into the Bernese Oberland some fifty years ago by Christian Fischer, a self-taught peasant-artist of

Brienzi. But he was more peasant than artist, detested working indoors, and his ambition did not extend beyond carving rings for table napkins, cutting wooden egg-cups, and adorning them with flowers. He was also a musician and village bone-setter, and altogether a man of versatile genius. But his great merit was being the creator of a new industry, for though Fischer did no great doings himself, he put into practice a valuable idea, and founded a school. It is hardly necessary to say that he died in poverty. Inventive geniuses, unless they have business capacity, generally do die in poverty. Peter Baumann, of Grindelwald, and a man named Flenz, belonging to the same country, improving on Fischer's idea, began the making of those charming Swiss chalets, now so popular, and which it is now almost *de rigueur* for tourists in Switzerland to purchase. What was more natural than for these peasant-artists to model, first of all their own picturesque houses with their overhanging roofs, their quaint galleries, their painted ornaments and carved figures, brown with age, standing on a plinth of white stone, overshadowed with trees, within sound of a rushing torrent, and sheltered from avalanches and the north wind by the rocky rampart of some Alpine height?

Peter Baumann, who seems to have been more thrifty and steadfast than his predecessor, settled at Meyringen and taught his art to his three sons, one of whom, Andreas, became the *facile princeps* of wood-carving. His work is deemed unapproachable, and his bouquets of roses still serve as models for aspiring sculptors. The success and celebrity acquired by the Baumanns caused the industry to spread, and wood-carving soon became the winter occupation of every householder in the vale of Hasli. But there was no regular market for their productions, their only customers were casual visitors, their only agents hotel porters and small shopkeepers, who took the lion's share of the profits. The trade wanted organising, in fact, and, after several tentative efforts in this direction, the Brothers Wirth established their extensive workshops, where several hundred sculptors of the Oberland now find regular employment. In this industry, as in almost every other, the best results are obtained by a division of labour. Every carver has his or her speciality. Some prefer to shape groups of animals, others like better plants and flowers, others again take to building miniature chalets, and making curious caskets, and what they like the best is generally the best done. Elaborate artistic furniture is also made in great variety in the establishment of the Brothers Wirth. In 1862 the industry had become so important that the Cantonal Government deemed it expedient to found a school of design at Brienzi, which is maintained by the State, the communes, and the fees of pupils, the last, however, being little more than nominal. In 1869 a master modeller, maintained in like manner, was appointed for the instruction of the carvers of Interlaken. The pay of a sculptor varies from two francs a day for beginners to five francs for the more expert, among whom is a large proportion of women, their natural tastefulness and deftness of touch making them formidable rivals to the men. Brienzi is the headquarters and chief mart of the trade, which has entirely changed the character of the town, and gives it an appearance of prosperity that in former years was conspicuous by its absence. The number of male and female sculptors employed at Meyringen and Brienzi amounts to 2,500, and their industry brings into the district some two million francs a year.

Successful enterprise is always a healthy and stimulating influence, and the success of wood-carving at Brienzi suggested the idea of making parqueterie and chalets at Interlaken. The former has already grown into a large business, the annual production of one establishment alone amounting to nearly 700,000 square feet of parqueterie, valued at half a million francs. Chalets are made for use, not for show, in parts, and, the parts being numbered and arranged to fit without trouble, a man may order a house by post, have it delivered by rail, and enter into possession, all within a few weeks. Attempts have also been successfully made to turn to account the indigenous stone of the country—variegated marbles, which are found in great variety, as also a soft stone, peculiar to the Oberland, which, while easily worked and susceptible of a high polish, acquires by exposure to the air an adamantine hardness, and has the further quality of being almost indestructible by fire.

## WORKS IN PROGRESS.

**Messrs. J. & R. Morley**, of Wood Street, having decided to take advantage of the system of the General Hydraulic Power Company, have instructed Messrs. R. Waygood to alter their present lift to work from the high-pressure mains, and to erect a new hydraulic lift, to be worked by the same power. The same firm also have in hand a steam-power lift for Messrs. Morley's premises at Leicester, and recently erected hydraulic lifts in their premises at Nottingham.

**Messrs. C. Isler & Co.** have just completed a 126 feet deep artesian bored tube well 4 inches in diameter, at Leicester, obtaining from it a supply of water at the rate of 2,500 gallons per hour. They have completed an artesian bored tube well at Taunton for a brewery, 196 feet deep, 5 inches in diameter, yielding at the rate of

2,000 gallons per hour. Both of these are in the new red sandstone formation.

**Messrs. Archibald Smith & Stevens**, of Janus Works, Queen's Road, Battersea, are erecting at the new Hibernia Wharf (Messrs. Humphrey Bros.) a complete set of hydraulic lifting machinery. This is one of the largest wharves on the south side of London Bridge, and the whole of the machinery is to be worked in connection with the Hydraulic Power Company's mains. The work is now approaching completion.

**Haselbury, near Crewkerne.**—The third bell of this ring has been recast, and the whole of the bells (five) refitted and rehung by Messrs. Llewellyns & James, Bristol. Inscription: "J. A. Caley, M.A., vicar; T. A. Rawlins, H. Hole, churchwardens. Recast A.D. 1884."

## LEGAL.

### Leeds Assizes.

(Before Mr. JUSTICE MANISTY.)

### CHORLEY v. CROSSLEY.—ARCHITECTS' FEES.

This case was one in which the plaintiff, an architect practising in Leeds, sought to recover the sum of 86*l.* 5*s.* 6*d.* balance of account for services rendered in connection with two arbitration cases, in which the plaintiff had appeared in the defendant's behalf. The contention on behalf of the defence was that the charges were excessive, and that they were greater than the plaintiff had agreed to make. After hearing the opening statements and the plaintiff's evidence, and before any other witnesses had been examined, the judge suggested that the plaintiff should accept in settlement of his claim the sum of 50*l.*, in addition to the 29*l.* 10*s.* which the defendant had paid into court. This was agreed to, His Lordship marking his opinion of the weakness of the defence by certifying for all costs against the defendant, including those of a special jury.

## NEW BUILDINGS.

**Canterbury.**—The Sidney Cooper School of Art is undergoing a process of partial reconstruction. The wall which formerly divided the building into two narrow galleries has been removed, and there will be in future a spacious hall, which by the use of curtains may be divided into six classrooms. The contract is being carried out by Messrs. Gentry & Son, the amount of their tender being 693*l.* 10*s.* Mr. J. G. Hall, of Canterbury, is the architect.

**Huddersfield.**—The corner-stone of a school in connection with the United Methodist Free Church, Bentley Street, Lockwood, has been laid. The building, which has been designed by Mr. B. Stocks, architect, Huddersfield, comprises a large assembly hall, with gallery, and classrooms opening on the hall. In addition, there is to be an infants' classroom and a vestry and school-keeper's house.

**Snow Hill Arcade, Birmingham.**—A new arcade connecting Snow Hill and Slaney Street has been commenced. The style adopted is Early Gothic. The frontage to Snow Hill will consist of large shops four storeys high, divided by a bold Gothic arched entrance. The elevation will be of an ornamental character, buff-coloured glazed bricks, Minton's tiles, parti-coloured stone, ornamental red brickwork and terra-cotta, ornamental metal-work, &c., being introduced. The elevation to Slaney Street will be plainer. The shops in the arcade will also be of somewhat plain design, glazed white brick facings, gauged brick arches, moulded brick cornices, bay windows, &c., being introduced. A large enriched centre gable filled in with panellings, ornamented tiles, &c., will emphasise the Snow Hill front. The architect employed is Mr. J. Statham Davis, of Birmingham.

**Hastings Memorial Homes.**—Some houses are being erected at Collinton, near Edinburgh, under the will of the late Marchioness of Bute, which will be used as homes for widows or orphans of British military officers. One of the blocks is about ready for occupation, the second is rapidly advancing to completion, and the third will be ready before the end of the autumn. Each block contains two houses, and each house contains two public rooms, three bedrooms, servants' rooms, and all the other accommodation which is in these days provided in the best finished houses of from 50*l.* to 70*l.* of yearly rental. Consisting of two floors, the houses are designed in the late Mediæval style of cottage architecture, when timber was largely used. The first floor and the chimney-stacks are all constructed of masonry; but the upper floor consists of half-timberwork, filled up with brickwork, cemented on the face. The roofs are covered with red tiles. Each of the blocks is different in design; but in all of them the upper floors, which are partly in the roofs, develop themselves into a number of gables, which are finished in a more or less ornamental manner. The interior of each house corresponds, as regards accommodation, appointments, and finish, with the pleasing aspect

of the exterior. The drawing-room and dining-room on the first floor are spacious apartments, and have been treated in conformity with the style of the architecture, the fireplaces being of massive woodwork finished in a highly-artistic manner. The three bedrooms on the upper floor are hardly less spacious and handsomely treated. The kitchen and the other apartments on the ground floor are spacious and well equipped. Large and well-lighted and well-ventilated bath-rooms, hot and cold water, and the other modern requirements in first-rate dwellings, have been provided. The drainage has been attended to under the direction of the Sanitary Association, and the grounds are to be laid out by the trustees. In situation, style, and cheerfulness of interior, these houses will be regarded by most people with admiration. The outcome of a beneficent spirit, they form a memorial of interest and usefulness. The architect for the houses is Dr. R. Rowand Anderson, of Edinburgh.

### CHURCH BUILDING AND RESTORATION.

**Blyth.**—The foundation of St. Cuthbert's Church has been laid. The site is west of the old building, and, when completed, the two buildings will be within one and the same enclosure. There is no record of the consecration of the old church, consequently the vicar intends to devote it to secular purposes. Only part of the new site is at present being built upon, and the church now in course of erection, which is of stone, and built in the fourteenth-century style of architecture, will, when completed, seat about 370 persons, and will cost 3,000*l.*, nearly the whole of which sum has been raised. Mr. W. S. Hicks, of Moseley Street, Newcastle, is the architect, and Messrs. E. & J. R. Taylor, of Benfield-side, the contractors for the main portion of the work.

**Higher Audley.**—The foundation-stone of a new church in Higher Audley, Blackburn, dedicated to St. Matthew, has been laid. The building is in St. Thomas's parish, which contains nearly 18,000 people. The new church is to cost 7,000*l.* Messrs. W. C. Habershon & Co., London, the architects, have designed a cruciform structure in the Decorated Early Fourteenth Century style. It will have a nave, side aisles, transepts, chancel, organ chamber, and vestries, the internal fittings being of varnished pitch pine, and will accommodate 710 persons.

**Newbury.**—The Congregational church, Northbrook Street, has been reopened after undergoing renovation, which has been carried out under the direction of Mr. Walter H. Bell, architect, by Mr. J. Hopson, contractor. The cost of the work has been about 500*l.*

**Nunnington.**—The ancient parish church of Nunnington, near Helmsley, has been reopened after restoration, carried out under the direction of Mr. Ewan Christian. The chief work of restoration has been the erection of substantial open roofs to chancel and nave, the removal of the ugly, low whitewashed ceilings; the rebuilding of the much-decayed north wall, and also the large vestry and porch; the erection of a chamber for a new organ; opening out and reroofing the tower and restoring the old pinnacles; facing the unfinished west arch of the tower with dressed stone; reflooring and reseating the church—the cumbrous old reading-desk and high box pews having all been banished from the chancel; and the introduction of a new heating apparatus. The contractors for the restoration were Messrs. Langley Brothers, of Hunslet, Leeds.

**Dewsbury.**—The memorial-stones of a Wesleyan Mission chapel in Eastborough, Dewsbury, were laid on Saturday, the 16th inst. The building will accommodate 300 worshippers. The designs and plans are by Mr. F. W. Ridgway, architect, of Dewsbury, under whose supervision the works are being carried out.

### GENERAL.

**Mr. G. S. Aitken, F.S.A. Scot.,** architect of Dundee, has in preparation an illustrated and descriptive work upon the three Scottish abbeys of Arbroath, Balmerino, and Lindores. Measured drawings and views will be given, and the work will cover a field not hitherto occupied.

**Mr. Vincent W. Voisey, F.R.I.B.A.,** has prepared plans for the erection of a parsonage house in connection with St. Matthew's Church, Moorfields, Bristol.

**The Exhibition of Decorative Arts,** which is the third of the series promoted by the Central Union, has been opened in Paris. It is restricted to pottery, and the principal attraction is the division assigned to the Sevres factory. M. Carrier-Belleuse, the present director, has a gallery for his own works.

**The Bristol University College Authorities** have arranged a special course of instruction for students intending to become architects. Among the subjects included are the history of

architecture, and the theory and practice of building. The engineering department also includes special courses for civil, mechanical, and electric engineers or surveyors.

**Herr Maurice Thausing,** the Professor of Art History in the University of Vienna, has been drowned in the Elbe. His principal work is a Life of Albert Dürer, of which a translation was lately published in England.

**Mr. A. B. Brady, C.E.,** has been awarded an honorarium by the Maldon Union Sanitary Authority for his services in connection with the Burnham and Tillingham sewerage works.

**An Exhibition** of pictures and sculpture by French artists will be opened on Monday in the Dudley Gallery.

**The New Museum** in Newcastle-on-Tyne, which was opened on Wednesday, was designed by Messrs. John Wardle & Son.

**The Autumn Exhibition** of the Birmingham Royal Society of Artists will open in the beginning of next month. The private view will take place on September 3.

**Mr. Boehm** has modelled two busts of the late Duke of Albany. One is said to be intended for the Royal Mausoleum at Windsor and the other for Balmoral.

**Mr. T. J. Steel,** of 31 Gracechurch Street, is now in possession of the site on which the Northumberland Avenue Hotel Company have been erecting their intended hotel, having purchased the site and the buildings on it.

**A Tower and Spire** have been added to Holy Trinity Church, Bingley, from the designs of Mr. Norman Shaw, R.A., at a cost of 1,400*l.*

**Clergy and Choir Stalls of Oak** have been introduced into the chancel of St. John's Church, Leamington. They are the work of Messrs. Jones & Willis.

**A Grotto,** from eight to ten metres high, has been discovered in a rock washed by the sea in the Morbihan by M. Gaillard. He has since continued his researches at low water, and found some human bones, ancient earthenware marked with allegorical figures, and coins believed to have been struck by the early Gauls.

**The York Architectural Association** held its closing meeting of the session last week, in the saloon of the Victoria Hall, Goodramgate. In the absence of Mr. W. G. Penty, president, Mr. Wm. Brown occupied the chair. The following officers were elected to serve on the executive for the ensuing session:—President, Mr. A. Pollard; vice-presidents, Mr. W. G. Penty and Mr. Wm. Hepper; hon. treasurer, Mr. Norman R. Yeomans; hon. secretary, Mr. B. Priestly Shires; committee, Mr. J. N. Braithwaite, Mr. H. C. Crummack, Mr. Geo. Benson, Mr. G. J. Monson, C.E., A.M.I.C.E., and Mr. W. H. Smithson. Votes of thanks were unanimously passed to the retiring committee and to the chairman for presiding.

**The King of Bavaria** has increased the list of his already numerous mountain palaces and castles by the purchase of the ruined castle of Falkenstein, situated on a steep mountain cliff near Weissbach, on the Tyrolese frontier. It is intended to rebuild the place, remodelling it to suit modern ideas of a pleasant royal hunting seat. As a preparatory step, a large body of labourers and artificers is employed making a carriage road which shall give an easy access to the eyrie where Falkenstein is perched.

**A Welsh Church Commission** has recommended the erection of ten new churches and several mission chapels in the deanery of East Gower, Glamorganshire. In most of the cases sites have been given or promised.

**The Roman Catholic Church** built by the Marquis of Bute at Old Cumnock, Ayrshire, has recently been fitted throughout with the electric light. There are in all about seventy glow-lamps of twenty candles each.

**A Harbour** is to be constructed on the Lincolnshire coast at Sutton-le-Marsh. The works, which will be under the superintendence of Sir John Coode, will consist of an outer harbour of 14 acres, leading by a lock of 50 feet in width to an inner dock of nearly 10 acres in extent. The outer harbour will be protected by a north and south pier, respectively 517 and 418 yards in length, with a lighthouse on the former, and an entrance on the latter one, which is the most sheltered.

**A Door Spring** has been invented in America which breaks the force of the shutting blow by connecting the spring to the piston-rod of a small air cylinder, so that the momentum of the door compressing the air in this cylinder checks the motion of the piston by an elastic resistance, which is removed after a moment by the gradual escape of the air through an opening too small to allow its sudden liberation; but, when released, allows the spring to close the door with a firm push over a distance of two or three inches.

**The American Elevator Company,** of 38 Old Jewry, London, have received the contract for a first-class "Standard" hydraulic passenger-lift, to be placed in the residence of Mr. Burns, 69 Brook Street, W. This will be of similar pattern to those which are in general use in the United States for private houses.

# SUPPLEMENT

TO THE

# ARCHITECT.

## CONTRACTS, COMPETITIONS, AND TENDERS.

LONDON, AUGUST 23, 1884.

### COMPETITIONS OPEN.

**BIDEFORD.**—Sept. 22.—The Trustees of the Bideford Bridge Trust invite Competitive Designs for the Erection of a Block of Buildings suitable for a Post Office on site of Premises in High Street. Premiums of 20*l.* and 10*l.* The cost of carrying out any of the Designs not to exceed 800*l.*

**BOMBAY.**—Nov. 6.—The Municipal Commissioner of Bombay invites Designs and Estimates for a New Municipal Hall and Offices, which must be sent to his Office by Twelve noon, on Nov. 6. A Premium of 5,000 rs. will be given for the Design most approved of by the Commissioner, with the assistance of a Committee of the Corporation; 3,000 rs. for the second, and 2,000 rs. for the third. The total cost of the buildings is not to exceed 5 lacs (5,00,000 rs.). Mr. E. C. K. Ollivant, Municipal Commissioner's Office, Bombay, or at Messrs. E. W. & R. Oliver, 1 Corbet Court, Gracechurch Street, London.

**REDRUTH (CORNWALL).**—Sept. 13.—*School.*—The Redruth School Board offer a Premium of 25*l.* for the best Plans (Elevation and Detailed Drawings), to be selected by themselves, for a School, to be erected at Trewrigie, Redruth, to accommodate 700 Children (350 Boys and 350 Girls and Infants). Total cost not to exceed 3,500*l.* Mr. Charles Bawden, Clerk, Heanton Place, Redruth.

**STOCKPORT.**—Oct. 1.—Designs are invited for Public Baths. Premiums of £50, £30, and £20. Mr. Walter Hyde, Town Clerk, Stockport.

### CONTRACTS OPEN.

**BATLEY.**—Aug. 30.—For a Warehouse in Tichborne Street, Staincliffe, Batley. Mr. J. T. Law, 64 Commercial Street, Batley, Architect.

**BIRMINGHAM.**—Aug. 28.—For Erection of Kitchen and other Buildings at the Workhouse. Mr. W. H. Ward, Architect, Paradise Street, Birmingham.

**BLACKBURN.**—For Building St. Barnabas' Church, Addison Street. Mr. William S. Varley, Architect, 15 Richmond Terrace, Blackburn.

**BRIDFORD.**—Aug. 23.—For Erection of Brick Chimney and Buildings, Fair Ground. Mr. J. H. Cox, Borough Surveyor, Town Hall, Bradford.

**BRIDPORT HARBOUR.**—Sept. 2.—For Building Ten Houses. Messrs. Prior & Alexander, Architects, 17 Southampton Street, Bloomsbury Square, W.C.

**CLAINES.**—Sept. 4.—For Construction of Pipe Sewers, Manholes, Receiving Tank, Engine House, Filter Beds, Roads, Fences, and Works in connection with the Sewerage Scheme of the District. Mr. A. H. Parker, Surveyor, 5 Foregate Street, Worcester.

**COLCHESTER.**—For Building Fourteen Cottages. Mr. F. E. Morris, Architect, West Stockwell Street, Colchester.

**CORNWALL.**—Sept. 2.—For Erection of Viaduct in Masonry at Guildford, Hayle, and at Redruth. The Engineer, Paddington Station.

**DARENTH.**—Aug. 25.—For Enlargement of Gasworks at the Asylum for Imbeciles. Messrs. A. & C. Harston, Architects, 15 Leadenhall Street, E.C.

**DEWSBURY.**—Aug. 27.—For Building Model Lodging House, Westgate. Messrs. Smith & Tweedale, Architects, Manor Street, Dewsbury.

**FARNLEY.**—Sept. 2.—For Rebuilding St. Michael's Church. Messrs. Chorley & Connon, Architects, Leeds.

**HEYWOOD.**—Aug. 25.—For Building Fireproof Mill. Messrs. Potts, Pickup & Dixon, Architects, 1 Princess Street, Manchester.

**LEEDS.**—Aug. 27.—For Taking Down and Rebuilding House and Shop. Mr. Abraham Wood, Architect, Menston, Wharfedale.

**LETTERKENNY.**—Sept. 1.—For Additions to District Lunatic Asylum. Mr. Morley, Building Surveyor, Commercial Buildings, Dublin.

**LINCHMERE.**—Aug. 30.—For Building Board School and Teacher's Residence. Mr. Edward Eames, Surveyor, Linch, near Midhurst.

**LINCOLN.**—Aug. 25.—For Excavation, Sewering, Constructing Manholes, Ventilators, and Gullies, Fixing Kerbs, Forming Carriage Ways, &c., in Extension of West Parade from Orchard Street to Hungate. Mr. R. A. Mac Brair, City Surveyor, Lincoln.

**LOCHMADDY.**—Aug. 30.—For Additions to Hotel. Messrs. Kinnear & Peddie, Architects, 8 St. Charlotte Street, Edinburgh.

**LOW SEATON.**—Aug. 23.—For Building Good Templars' Hall. Mr. G. D. Oliver, Architect, 41 Pow Street, Worthington.

**NELSON.**—Aug. 26.—For Building Weaving Shed and Premises. Mr. Thomas Bell, Architect, 14 Grimshawe Street, Burnley.

**REPTON.**—Aug. 26.—For Building School and Classrooms. Mr. B. Scott Currey, Derby.

**ROCHDALE.**—Sept. 1.—For Additions to Chapel. Mr. Benjamin Heape, 7 Baillie Street, Rochdale.

**SEAHAM HARBOUR.**—Aug. 30.—For Building Co-operative Store, Manager's House, and other Buildings. Mr. George R. Forster, Architect, Seaham Harbour.

**SHEPTON MALLET.**—Aug. 30.—For Building Sexey's County School at Douling. Mr. G. J. Skipper, Architect, Ople Street, Norwich.

**SNATH.**—Aug. 25.—For Strengthening Roof and other Work at Wesleyan Chapel. Mr. W. Watson, Architect, Barstow Square, Wakefield.

**SOUTH SHIELDS.**—Sept. 1.—For Erection of Dwarf Wall with Iron Palisading and Gardener's House, at the Lawe. The Borough Engineer, Chapter Row, South Shields.

**SPEN COLLIERY.**—Aug. 25.—For Building Chapel. Mr. Thomas Southron, Architect, 70 King Street, South Shields.

**STRATFORD.**—For Building Nine Houses, Cedar Road. Mr. W. Bigg, 287A East India Road, Poplar, E.

**SUNDERLAND.**—Sept. 1.—For Building Methodist Schools, Chester Road. Mr. Joseph Shields, Architect, Blackett's Buildings, Sunderland.

**TODMORDEN.**—Sept. 26.—For Construction of Reservoir, Ramsden Clough. Mr. James Farrar, C.E., Market Street, Bury.

**TUNSTALL, NEAR ACLE.**—Sept. 3.—For Building Stable, Wagon Lodge, Piggeries, &c., Church Farm. Mr. Arthur J. Lacey, Architect, Orford Hill, Norwich.

**WALSALL.**—Aug. 23.—For Erection of Farm Buildings, Brockhurst Farm, for the Corporation. Mr. Samuel Wilkinson, Architect, Town Clerk, Bridge Street, Walsall.

**WILSDEN.**—Aug. 25.—For Building Mill, Shed, Offices, Engine and Boiler Houses, Chimney, &c. Mr. Wilson Bailey, Architect, 9 Market Street, Bradford.

**WIMBLEDON.**—Aug. 26.—For Building Press House, Cake Shed, and Plant for Treatment of Sewage Sludge. Mr. W. H. Whitfield, Local Board Offices, Broadway, Wimbledon.

**WORKINGTON.**—Aug. 29.—For Additions to Camerton School. Mr. George Watson, Architect, 3 St. Andrew's Place, Penrith.

GRUNDY'S PATENT  
WARM-AIR  
VENTILATING FIRE GRATE.

The novelty, superiority, and advantage of this patent consist in the heating surface being greater than any other Fire-grate introduced to the public. It is very simple in construction, and is made in the form of a Stove, the back of which is semicircular in shape, with gills behind and smoke-nozzle on top, all cast in one piece. The same can be attached to any design of a Register or Stove front. It is very suitable for schools, class-rooms, waiting-rooms, hospitals, offices, dormitories, and dwelling-houses, from the cottage to the mansion. Design and specification post free on application.

TESTIMONIALS.  
"9 Victoria Chambers, Westminster, S.W."  
"June 10, 1884."  
"Sir,—I have much pleasure in testifying to the efficiency of your patent Warm-Air Fire Grate. It has been very successful, and given every satisfaction where I have used it."  
"Yours, &c."  
"JAMES WEIR, F.R.I.B.A."

"To Mr. Grundy."  
"Baptist Chapel, Clapham Common, London. Richard Webb, Pastor, 10 Grafton Square."  
"February 15, 1884."

"DEAR MR. GRUNDY,—I have pleasure in testifying to the excellency and efficiency of your patent Fire-Grate. It is the most charming invention for heating a large room I have ever known. I shall have pleasure in showing it to anyone who wish to have their schools or rooms pleasantly and efficiently heated."

From James Garry, Esq., Architect, West Hartlepool, July 1884.

"DEAR SIR,—I have very great pleasure in stating that the first stove, or patent warm-air ventilating fire grate, adopted by me in school at Seaton, and a second in a Cocoa Palace, have given such satisfaction that I now order eleven to be inserted in New Upper Grade Schools in course of erection at West Hartlepool. They are the most economical, efficient, and easily managed stove at present before the public."

"Mr. John Grundy."  
Apply to JOHN GRUNDY, 30 Duncan Terrace, City Road, London.  
Works—TYLDESLEY, near MANCHESTER.

ACCEPTED DESIGN FOR ADMIRALTY & WAR OFFICES

BY MESSRS LEMMON & LEMMON

# The Architect.

## LIVERPOOL CATHEDRAL.

OR some years back the citizens of the important city of Liverpool have been engaged in bringing into form a scheme for building a cathedral, and within the last week or two the first step has at length been taken towards determining the architectural design of the edifice. A general invitation had been issued to architects to send in specimens of their work, by means of which an eminent ecclesiastical practitioner, called in for the purpose, was to select a small number to engage in a competition. As has

been already announced, a very large number of candidates answered this invitation, and Mr. EWAN CHRISTIAN, as the referee, has now made his selection of competitors. Speaking broadly, it may be said that the gentlemen thus chosen are so many High Church Gothic architects. It is intended, therefore, that the new cathedral shall be of academical Mediæval design, of what is considered to be the most advanced type. Those who understand the subject are enabled to anticipate pretty exactly what will be the nature of the result, by recalling to mind what took place in the similar competition which was instituted a few years ago for a so-called cathedral at Edinburgh. Another more recent case, equally instructive, is that of the cathedral of Truro now in process of building. We do not in any way desire to raise an objection to what was done either at Edinburgh or at Truro; but the position of Liverpool socially is so peculiar, that it seems desirable to inquire pointedly what it is that the public of that great city really wish to have. To put the case familiarly, the people of Liverpool may have either a Westminster Abbey or a St. Paul's, and it is for them to choose which they prefer. Up to the present moment it would seem to be settled that it is to be a Westminster Abbey; no one is entitled to say nay to this if the local public say aye; but it may be interesting at any rate to explain that there are two sides to the question.

Conceding to Mediæval ecclesiastical architecture all that can be demanded in acknowledgment of its artistic graces, it can scarcely be denied that much of its interest, if not all, is derived from the existence of appropriate surroundings, or at least congenial associations. The charm which English people at large perceive in the remains of their own antiquity is a very pleasing incident in the national character, and especially in view of the radical change which has come over the mind of the community since the times to which such relics belong. But the virtue of this feeling depends entirely upon its genuineness; the introduction of mere imitation or make-believe, or, to speak plainly, sham, brings down the sentiment to the level of vulgar affectation. Now Liverpool is one of a number of great modern towns which have no Mediæval associations whatever; and, indeed, in connection with such an undertaking as the building of a cathedral, it may be called the chief of these, and the most uncompromising representative of all that belongs to them. We are not suggesting a case of conscience, or creed, or ecclesiastical politics, or anything of the kind; we are dealing with art alone, and the fitness of things artistic; and the question we put is simply this artistic question as one of common sense—Have the people of Liverpool really made up their minds to have for their cathedral an imitation Mediæval abbey church? Of course they cannot have a real one.

A comparison between the City of London, with its essentially modern cathedral in the midst surrounded by WREN'S modern churches, and some old town like York or Chester or Canterbury, pervaded everywhere and dominated everywhere by the crumbling remains of obsolete antiquity, is one which cannot but provoke in these days many a strange reflection. There is something singularly incongruous, in spite of all that romance can say, in seeing the bustle of our commercial life carried on under the gray walls of churches whose age is counted by centuries; and, if the truth may be told, it is when such venerable relics are supported by something like the remains of their own original surroundings, worn-

out old dwellings in grass-grown streets, occupied by people half awake, whose business seems to be a dream, that the holiday-maker can best enjoy the unwonted sense of imperturbable rest, just as some poetic people, for the sake of the peacefulness of it, wish they were dead. To anyone who has ever seen Liverpool, it scarcely requires to be said that the great representative city of modern commerce has nothing at all in common with the solemn passivity which thus accords so well in character with the charms of genuine Gothic building.

The magnificent St. George's Hall, which is the boast of Liverpool, is probably more characteristic of the city in its grand commercial pride than any other edifice in England would be. Many of the citizens might be not a little surprised if they were to be told that there are certain architectural authorities who would infinitely prefer to have had St. George's Hall built in some sort of sham Gothic. We used to be told not very long ago that there was nothing in the whole range of structural beauty and grandeur which could not be better accomplished in such Gothic than in any other mode; and there are many estimable architects in England now who would design St. George's Hall, if not in the manner of the London Law Courts, certainly in the so-called style of Queen Anne as a substitute. But, nevertheless, we may take leave to say of the majestic building of ELMES and COCKERELL, that if ever the right thing was in the right place, that is the right thing in Liverpool. The same may be said, in their degree, of the new Art Gallery and Library, the Exchange, and many other buildings; they are all essentially right because all essentially modern like the city itself. To invite Liverpool to hark back to the Middle Ages, seems to be on the face of it absurd. There are certain sham Gothic façades to be seen, no doubt, in the Liverpool streets; but, especially now when the fashion has gone out, is there anybody to say they are appropriate? The question before us, therefore, is whether a great cathedral church in imitation of the churches of the thirteenth century would be any better suited to the genius of the place. Liverpool people may regret legitimately, if so minded, that their town does not happen to possess, like Chester, a real cathedral of the Middle Ages, upon which they might spend their money freely, as no doubt they would, for the sake of old times; but if they must consequently be content with a brand new cathedral, in fact a nineteenth-century cathedral, are they not entitled to ask why it cannot be made a genuine thing instead of an imitation?

In quoting St. Paul's in London as a familiar alternative, we may be met with the inquiry whether a St. Paul's in Liverpool would not be itself an imitation. The answer is that it would not; and here, indeed, lies the force of the contrast. Between the date of Westminster Abbey and that of St. Paul's, apart altogether from the interval of time, there is, as all the world knows, a great gulf fixed, a social gulf between two distinct civilisations, that of Mediæval Europe and that of Modern Europe. Westminster Abbey and a thousand other genuine Gothic churches throughout Europe were built in the style belonging to their age; St. Paul's and a thousand others since have been built in the style belonging to theirs. Addressing ourselves as we are more to the outside public than to the architectural profession, we find it the less necessary to adduce proofs of a proposition which is self-evident.

There is no need for drawing comparisons between Mediæval art and modern in respect of merit. *De gustibus non est disputandum*. Not a word of disparagement of Gothic design is intended to be even implied in our argument, nor a word of preference for Classic on its own account. But we have now had so much, so very much, of imitation Gothic in our new churches that we may surely venture to hint that, if a fair opportunity for indulging in a change of style were to offer itself, there are many weary minds all over the country which but too gladly would entertain the idea of attempting, if only as an exception, a single Classic example. Is the Liverpool Cathedral, then, or is it not, such a fair opportunity? Liverpool is intensely modern, immensely wealthy, entirely commercial; as the seat of a new bishopric it stands alone, or is to be associated with only one other; when it desires to build a cathedral, it is altogether on its own social ground; and if architecture, even in a cathedral, ought to tell the story of its own time, the simple question is—How shall this rule be applied to Liverpool by Liverpool?

It is not at all unlikely that some of the eminent ecclesiastical architects whom Mr. CHRISTIAN has selected as competitors will be found to go a good deal farther than the

Liverpool people expect in the exercise of a natural academical desire to produce a thoroughly high-class and perfect project. Not only may the church itself be modelled on the most inappropriately and even inconveniently monumental lines that can be discovered in Mediæval authenticity, but we may have attached to it, for instance, a whole conventual establishment—cloisters for the meditation of the clergy, and a cloister garth for their burial; sacristy and almonry; refectory, buttery, and dormitory, if not for the clergy, for the white-robed choristers; and an abbot's lodging for the dean, which he would certainly decline to live in. We do not say this disrespectfully at all, but would rather ask whether the addition of all these counterfeits would not be perfectly rational, and indeed commendable, in designing a counterfeit abbey church of the thirteenth century. On the other hand, if what the people of Liverpool really want is a grand monumental church worthy of the dignity of their great commercial city at the close of this nineteenth century, might it not be infinitely more appropriate to the occasion to forego altogether the questionable satisfaction of imitating the models of wholly different times, and try what can be done in the natural manner of their own business and their own age?

### ENGLISH RENAISSANCE ART AS SHOWN IN THE PUBLIC OFFICES' DESIGNS.

[BY A CORRESPONDENT.]

THE designs in the Government Offices' competition may fairly be held to represent with tolerable exactness the position of Renaissance architecture in Great Britain at the present day. Out of nine designs for this prominent public building, eight are in this style, and the authors of the ninth have sent a most picturesque sketch of a translation of their Gothic elevation into a transitional form of Renaissance. The process of selection by which the architects who competed have been chosen may no doubt have shut out many able and original artists, but still those who have been included may be considered as representative of the profession as regards architectural style. Without attempting in every case to point out our remarks by reference to individual designs, we propose briefly to consider at what level the English knowledge and practice of that phase of modern architecture which originated in Italy in the fifteenth century appears to stand, judging from the collection of drawings now open at Spring Gardens.

In matters of fine art we have certainly not yet bridged the Channel. Our painters are but little influenced by that development of their art which has been produced by the exertions of contemporary artists of the French school, and the same thing may be said of our architecture. The influence of INIGO JONES, WREN, HAWKSMOOR, and CHAMBERS is more traceable at Spring Gardens than that of the powerful and highly-cultivated group of modern architects who have recast Paris within the last half-century. No trace, or but few traces of neo-Grec can be detected, and this perhaps is the more remarkable as the completion of that very conspicuous public building, the details of which are much influenced by modern French art, which has been for years in progress in Belgium, has lately attracted public notice. We might have expected that the competitors would—some of them at least—have been tempted to take the Palace of Justice at Brussels as a model. Finer even than French work, but less known, is the architecture of the Renaissance school in Germany and Austria. Yet though Vienna and Berlin offer a remarkable series of great works, they do not seem, so far as their features are distinctive, to have suggested much to our English designers.

Under such circumstances as these individuality at least is to be expected, but with it local or national defects are liable to be preserved, and this has been the case in the competition designs. A great deal of modern architectural work in England has failed to rise above the level of commonplace mediocrity; it is often incorrect, or, if free from blemishes, devoid of interest; and accordingly in several of the elevations exhibited we find but a low level of excellence is reached. For features which in themselves are not strikingly beautiful, and which have become hackneyed by their constant use in buildings of little or no importance, others should be substituted which are more refined or less familiar, if a composition is to be worthy of the dignity of a great public work; but, in several instances hardly any attempt has been made to do this. We could point

out windows, bays, arches, &c., which are the very counterpart of what is in use in Belgravia and Tyburnia; introduced where a little more thought and a more thorough mastery of the resources of the style would have led to the employment of something better, to the infinite advantage of the design. If on the one hand much of the work is too commonplace, on the other hand some of it displays a second English fault. It is too free. There are portions of designs not lacking in spirit and power of composition, where ornamental features and enrichments can be detected which are altogether too wild and fantastic, or else too careless and unstudied for the purpose of the building and the requirements of the site. We ought however in fairness to add that there are other designs in which the features are not as a rule hackneyed, and in which the dignity of the subject is well preserved, though in none is there an extraordinary command of the resources available for use in a monumental building.

One of the greatest difficulties which a designer has to encounter who arranges a Renaissance building for English use is the necessity for introducing ample light. In designs where fenestration is more relied on than the use of the Orders, it is absolutely essential, if the building is to be dignified, that the unpierced wall space should be considerable, and that its value should be emphasised. BARRY showed how to do this in his Pall Mall club-houses, but his example has not, at least to any great extent, influenced those competitors whose choice has fallen on what may be termed a fenestrated style.

English buildings of the seventeenth century were remarkable for the possession of certain good qualities, which have descended, as we are glad to recognise, to the present day. If WREN and VANBRUGH were deficient in their detail, they managed to impart to their work a degree of flexibility which is often wanting in the public buildings out of England erected at the same period, and they paid scrupulous attention to the sky-line. WREN's genius was never so well displayed as in his varied church towers and spires and in his glorious dome, which have bestowed upon the metropolis of England an architectural character eminently its own, and in those parts of the plan and the design which tend to give light and shade, variety and life to a building. In both these respects some at least of the competitive designs are remarkably successful. Messrs. ASTON WEBB & BELL stand highest in their treatment of sky-line, the more so as they have so disposed their plan that nearly the whole of their richly varied outline grows naturally out of the disposition of the masses of the work, and could not be affected by any such fit of parsimonious eccentricity as has cut off from SCOTT's Colonial Office the only features with which he intended to break the flat outline of his Whitehall front. In Messrs. VERITY & HUNT's design, the absence of high roofs and of a good and telling sky-line is a most unfortunate deficiency, and has been no doubt a main obstacle in the way of their success. Messrs. LEEMING have used features that will tell against the sky with considerable success, and their tower is one worthy to stand in the same city as those of WREN; but we think it is to be regretted that they have not ventured frankly upon the use of visible roofs, steep in pitch and highly enriched. These features, which are a recognised element of Renaissance design, impart life to the building, and do it in a very natural manner; nor is it to be overlooked in a country where such men as Mr. AYRTON sometimes bear rule over matters of taste, that it is less easy to omit them than it is to cut off the tops of towers.

What we have called flexibility is the good quality which we think is best illustrated by the designs sent in, and it is probably the most peculiarly English. The habit of designing chiefly in Pointed styles has given our architects at the present day a feeling of command over the masses of their buildings, and of familiarity with the value of balance as compared with absolute symmetry, which emancipates them to some extent from the trammels which the regularity of Classic design is apt to throw round the architect. Several of the designs show that their authors are well able to deal with the difficult problems involved almost of necessity in the Whitehall front of the building. Here the principal entrance cannot without difficulty be a central one, and the exigencies of site demand an unsymmetrical treatment. Several competitors have adopted the excellent expedient of throwing back part of their building and forming a half quadrangle, or large recess, next Whitehall, and have shown great skill in dealing with this feature. Messrs. LEEMING have not taken this course, but have occupied the whole length of this Whitehall frontage with a

comparatively unbroken mass of buildings ; but they have had the courage to divide this mass unsymmetrically, and, in our judgment, great skill is shown by the manner in which the rhythmical harmony due to equal spacing of openings and columns is kept up, while the irregularity already referred to is just enough accentuated to divide the front into two portions, continuous and connected, but to a great extent distinct. Indeed, we are disposed to esteem this as the most original and meritorious piece of handling in the whole design. In respect of flexibility, however, as well as in the good treatment of sky-line, the design of Messrs. WEBB & BELL is superior to that of any competitor.

It is interesting to note the fact that Renaissance has been selected by all but one of the competitors. Of course the influence of the site and surroundings points to it as desirable, but in the great Foreign Office competition for buildings to stand in the same neighbourhood there were a considerable number of good Gothic designs, and for the Law Courts there was nothing but Gothic. This circumstance points significantly and clearly to the fact that a great change in public taste is taking place ; and if there be any other deduction to be drawn from the considerations we have brought forward, it would seem to be the necessity of keeping abreast of the architects of France, Belgium, and Germany in their development of a style towards which public favour is turning, or perhaps we ought to say, returning.

### ON THE HILLS: A LANDSCAPE GOSSIP.

[BY A PAINTER.]

NINE hours from London, two miles uphill from the sea and the little watering-place, no carriage road within sight, and wandering tourists almost as rare as though they were angelic—so abrupt is the change of scene that at first a kind of mental giddiness seems to take hold of one. Instead of the dull roar that the myriad and hoarse-voiced city sends up all day and half night long, broken into hideous and aggressive nearer dissonance by hand organs, itinerant vendors, the neighbour's piano, the children from the mews, tradesmen's carts and visitors' carriages, what sounds break the stillness of the summer day here upon the hillside? There is the plashing of the clear stream that comes down from above, leaping fresh and clear over stone and turf as it hurries past the house, best and sweetest of fountains for man and beast. There are cheery sounds of farm life. In the morning, before the heat of the day, the cattle are driven up the hill, the poultry are fed and go clucking about, the very pigs grunt amiably. All through the afternoon into the evening you may hear the mowers as they walk one behind the other, cutting the lush grass in the meadows below. All about on the hills the bees are tuning their orchestra of tiny pipes over the gold and purple of gorse and heather ; the sheep bleat plaintively, and move by twos and threes into the strips of shade beneath the big limestone boulders. At evening shadow and coolness fall upon our slopes, the cows come down to be milked and stand about the stream lowing, the mown grass is brought up and added to the big stack that smells so sweet at nightfall. Then, as the hours go by, all sounds fall away little by little. Work is done and the lights are out, the hills loom high and mysterious, the mountain forms in face of us are dark and solemn, the air is so still that you hear the break of the tide upon the sands far below, and the continuous plash of the little stream that may not rest even beneath the stars. Nothing is so strange to a Londoner as the hush of night upon the hills, strange even to dread until he learns to lose the wonder and only to feel the peace of it.

Change of sound is one reason, then, for that mental giddiness I spoke of ; change of scene is yet at first more reversing of equilibrium. It is not immediately that the mind adjusts itself to intimacy with mountain and valley under the shifting splendours of cloud and sunshine ; the long-drawn horizon of the summer sea ; the vision of sunset upon distant crags ; the mystery of moonlight on the hills. It may be all very well for the modern sensational landscapist to content himself with an "impression," of which he is pleased to impart a second-hand version by aid of pigment and palette-knife ; with a true artist an impression will really be the last outcome, and, as it were, a fugitive combination of many and subtle antecedents of observation and perception. The actual vision may

be almost momentary, but thought is quick past counting, and enriches the moment's glance with unconscious detail gathered before. We all know how TURNER used to sit down before a scene by the hour and take it into his mental storehouse before he ever put brush to paper. And what I am driving at now is the point that a painter, be it with brush or pen, with colour or words, cannot truly perceive, and therefore cannot truly represent, the character and beauty of any scenery until he has shaken off the husks of the town life he has left behind him, and by slow degrees has drawn into his mind—has, as it were, assimilated—the beauty and the character of the scene with his art nature. It takes some time to learn to see in the full sense, which includes mental and bodily vision. If you tear down from London or Birmingham, or any of the manufacturing towns of the north, and next morning set up your easel amid the heather and the bracken and think you are going to make a faithful portrait of Cader Idris yonder, where he lifts his head, furrowed with many a winter storm, above the surrounding hills, you are very much mistaken. There will be a great deal of paint, and we shall all know what mountain you meant to portray if your outline is pretty true. But as for any worth in your work, the famous portraits of the PRIMROSE family were not further from the art of TITIAN than your imagery from the kingly crag. You do not know a human face at the first glance, though you may seize on one frequent expression ; and mountains are hard to know as human faces. Let your easel stay in the corner for a week ; take your note-books and wander over the hills ; sit for an hour or two at a time, and do nothing but *look*, with your mind wide-awake, at what Nature will show you. After that you may begin and do something worth while ; something more than a superficial daub, ignorantly incomplete ; something more vital than a laboured image, which can never be true because began at the wrong end of the subject, with a seeing eye but without an understanding heart.

And this is true not only of majestic scenery, but also of all natural beauty that has distinctive beauty and character in any large degree.

That brings one to another point. First, you must study scenery closely before you can paint it at all ; you must acquaint yourself with form and substance, and watch what light and shadow do with both in revealing and concealing, in blanching or in flushing, before you can interpret by art. You must know the detail in order to paint the general. Then comes the selection of subject. And here it is impossible not to wonder at the limited range covered by our landscape artists. There were some papers on the subject a while back in these columns which I read with interest, though not able always to side with the writer. But a main drift, if I remember rightly, was to chide our landscape men with the manifold aspects of Nature that they leave unrecorded. Such blame is no doubt deserved to some extent, though not nearly to the extent now as it was fifty years ago : for the power of representing atmospheric effects, and the influence of the literature of the day in its close observation of external nature, have immensely extended the range of subject. By range I mean, of course, not area, the result of travel, but variety the result of observation. Another point not sufficiently understood or insisted on is the faculty for perceiving what is most characteristic in any given scenery ; and not only this, but also what is the state of atmosphere, the conditions of light and shadow, which also are most characteristic, or rather which bring out most forcibly the characteristic beauty—the significance, so to speak—of any given scene or feature in a landscape. This faculty of perception is in some artists innate ; doubtless in TURNER it was so as to atmospheric conditions. Among living artists a direct and simple example would be the elder HINE in his water-colour pictures of the Surrey downs. A better instance would be the late JAMES RAVEN in his mountain studies in the English lake country, full of the mystery of shifting mists and storm-cloud. But with most artists this faculty of seizing the characteristic is of slow growth, the result of experience and endeavour ; above all, of a receptive imagination, which, while not eager to impress upon the face of Nature the consciousness of its own human moods and vagaries, is yet keenly sensitive to influences from without. One man will travel and bring back a folio of pretty sketches which tell you as much about a place as a popular guide-book that calls all strata, rock ; all hills, mountains ; all vegetation, trees—with no indication of the difference between a chalk and a limestone cliff, between an oak and an elm, between the

work of the earthworm and the upheaval of the granite foundations. Another returns with a lot of fantastic notes suggested by realities which they in no way resemble. Another, mayhap, sets you at once in the heart of things; he has seized upon precisely those traits which mark scenery as of one locality and no other. It may be a certain curve in the horizon lines of mountain or hill, or the way in which they stand shoulder to shoulder, or it may be the situation of picturesque towns, always on a hill with crown of towers, or always beside a river with span of friendly bridge; or the mode of building, or the set of houses together, or some detail of form striking because characteristic and frequent. All artists know what a factor in a landscape are the form and the colour of the house roof, tile or slate or thatch, deep-eaved or shallow, steep-pitched, gabled, many dormered, or simply sloped. Or it may be the growth of special vegetation, the waves of woodland, the beech-woods of Surrey, the fir forests and birch glades of Ardennes, the clambering pine woods of the Tyrol, the filmy cloud of olive on the ochreous soil of Tuscany, the group of cypress or solitary stone pine about the Campagna farm, with its faint mountain background. Or there may be distinctive peculiarities in the crops, or in the configuration of the cultivated ground, not noticeable at first, but imparting certain colours and lines to the land. What a difference it makes, for instance, whether the fields are divided by walls, or hedges, or hedgerow banks, or by nothing at all, as in parts of France during summer, where the cultivated land looks like a kaleidoscopic pattern of soft hues. So on, *ad infinitum*, one might cite the kind of minor details that are in landscape as the little personal traits in human character—characteristics on which a painter should seize if he would bring up the distinctive and familiar look of the country. But which he does seize—how often? Let us illustrate by example from scenery close at hand which has suggested this train of remark.

Here we are, then, dwellers in an old farmhouse (that would make the fortune of a novelist as a background to his drama) high up on Welsh hills above the Mawddach estuary, which twelve hours out of the twenty-four is a brimming loch, reflecting the changes of sky and earth, and the rest of the time presents a strange surface of rippled sand and winding streams and pools, full of the subtlest colouring. On that side, the hills are broken below by patches of quarried rock and masses of close wood, and above into curves of upland pasture, craggy knolls, scrub and heather. Behind and above again Cader Idris and his brethren lift their high lofty ridges of bare rock, furrowed with watercourses, and their steep sides that fill with purple shadow in the hollows. To the west the hills lessen to the sea cliff; on the eastward the horizon has the fine peaked wave line which in Wales gives a mountainous character and dignity to comparatively low heights. Into the shining river bed project curiously jagged ridges of bare rock and wooded knolls. On this side the water the hills are riven into flanking cliffs of pale rock and bosses of heather and gorse, walls of shelter to the narrow valleys or gullies on the inner side. Then the hills rise abruptly again with crag and boulder among the short turf, and purple and gold glories of gorse and heather. Highest of all, Diphwys looks over the estuary towards Cader, and takes the low drifting clouds on his brow. These are some of the main and well-known features of this scenery, so well known that apology might be needed for describing them, were it not done for the purpose of pointing out that not in the lake-like windings of the estuary, or the ridged form of the eminences, or the hanging woods on the cliffs is it that the especial character lies, but in the detail and in the combinations. The geological stratum strikes a key-note in the chord of colour—grey, not the warm grey of granite, but the cold grey of a slaty rock. Grey are the crags and boulders and serrated ridges that break out through the turf; with solemn grey rock are walled and roofed the lone farmhouses on the uplands; grey are the cosy nests set back against the cliffs, from which you hardly distinguish them save by the group of sheltering wind-blown trees beside the stream; of grey boulders and wedges are the dry walls and sheepfolds that map with straggling lines and knots the green hill sides. In districts of slate quarry this use of the grey rock becomes sad, even oppressive, though in the mountains it takes fine tones. But here the grey seems the natural and fit complement of the abounding green. Another characteristic fact is that the excessively broken nature of the ground and the narrowness of the valleys giving precarious room for the farmers' crops up in the hills, the grass meadow and patches of cereal eddy

in and out among the bossy knolls of wild rock and heather, here a wandering thread, and there widening into a sweet curve of flowerful greenness. The little fields of barley and oats run between the cliffs and fill with pale gold the available slopes and ledges. Along the high-lying valleys stony ways, footpaths rather than roads, go clambering up and down from farm to farm, crossed continually by the mountain streams that mark their downward course to the sea by freshening pastures and little oases of flowers and birch trees. The further end of the valley gorge is closed by a distant wave line of peaked heights, or oftener yet by the shining level of the sea. The curves of the Welsh coast bring many an unexpected view of the sea. After toiling up some craggy path between the cliffs you may find yourself suddenly looking over a breezy swell of turf and boulders to a dip in the hills, where, like a vision, spreads the lustrous sea bounded by a line of amethyst mountains, dreamy, far away. Sometimes, on a hot, still day, a weird white mist will float inland; like ghostly shapes the soft clouds pass between the parted hills, and gather and close until a deep bar of rolling whiteness, touched with iridescent gleams, shrouds all the lower heights, and above it Cader Idris and his peers rise solid but mysterious, strangely hued with pale jewel colour. You must have ascended pretty high to see this. Below you the mist thins to a vapour, and the sun glints through it on the farm pastures, where the mowers look like spectres bending to and fro at their toil.

These are a few of the summer aspects and details essentially distinctive of this part of Wales, and yet how many artists have recorded them? Not the men who pitch their sketching umbrellas about the mouth of the estuary and paint rainbow-tinted versions of the striking view up the Mawddach. Not the young painters, imbued with one corner of Mr. Ruskin's teaching to the exclusion of the rest, and who seem to have journeyed hither many miles only to copy a boulder and a tangle of brambles and bracken that they might have found within five miles of their northern town. There is one working away in sight of me now. Of course there have been and are artists whom the grander aspects of Welsh scenery have drawn to their highest efforts. ALFRED HUNT, for example, has done very fine work about Harlech and the spurs of Snowdon. He is one of the few landscape painters of the day who is not afraid to attempt record of intricate atmospheric conditions, having a fine sense of their fitness to the character of certain scenery. We only wish he would try his hand at a summer sea fog beneath Cader. We recall many a painstaking, many a pretentious picture gathered from the region of North Wales, which has told well enough on the walls of London exhibitions, but might have been set down in the catalogue as painted in any mountainous part of Great Britain and Ireland with equal claim to please. But with exception of the Welsh subjects by the ever-to-be-lamented DAVID COX, very little work remains in the mind that bears unmistakable cachet of fidelity by the selection of such characteristics of the scenery as I have indicated. The faculty for perceiving them has been wanting, or has been warped by false ambition, or false taste.

I have taken the distinctive marks of one locality merely as illustrative of a principle which applies equally to all scenery, namely, that a sympathetic and truly artistic landscape record must include—nay, must mainly depend upon—the characteristic; by characteristic meaning not merely the permanent features of a landscape, but the signs of the toil and the life of its human dwellers, and those combinations or conditions of atmosphere which are of an inherent unity with the scene. A careful analysis of TURNER'S work proves this; and a study of the landscape of contemporary artists who stand above the average level reveals always the perceptive faculty for the individual, the distinctive, the inherent.

On the atmospheric treatment of landscape much might be enlarged. I have but touched the point. It is here that the imaginative perception of character is tested, for selection here proves a power of reading the "soul in nature," to enter upon which would lead us from the simplicity of this discourse among the hills into an essay on æsthetic philosophy—from which may we and our readers be herewith delivered!

---

**The Dean of Wells** appeals for subscriptions to supply a memorial of Bishop Ken in the cathedral, and which will consist of the following works:—A memorial window, stalls and seats in the Lady Chapel, a reredos and ornamentation of stone screen, all being executed under Mr. Sedding's direction.

## THE DISCOVERIES AT LANUVIUM.\*

BY R. P. PULLAN, F.R.I.B.A.

THERE were two cities of Latium with names so much alike, that the similarity in spelling gave rise to extraordinary mistakes. These were Lavinium and Lanuvium. In some ancient MSS. the latter is spelt Lanivium, so that we can easily believe that they were frequently confounded with one another, to such an extent that their early history was by no means clear. Lavinium—now Pratica—lies in full Campagna only a few miles from the sea coast. I visited it some ten years ago in company with our late lamented colleague, Mr. J. H. Parker, and found it to be a miserable little village, with but few remains of antiquity. Inscriptions have, however, identified it as the traditional landing-place of Æneas, the progenitor of the Latin race—named after his wife Lavinia—and the chief city of the Latin Confederation. Lanuvium, on the contrary, is situate on a spur of the Alban hills, which juts out into the plain for a mile or more, some twelve miles inland. In the Middle Ages this was a much more considerable place than Pratica, so the inhabitants, presuming upon the aforesaid similarity of names, asserted that their town was the real landing-place of Æneas, gave it the name of Civita Lavinia, and actually inserted an iron ring into the outer wall of the fortifications—which they exhibited, and which their descendants still exhibit as that to which the great Trojan attached his galley. Although, had this been true, the whole of the Campagna would have been then under water, and the Alban, Volscian, and Sabine hills mere rocky islands, for Civita Lavinia is situated on a promontory some three hundred feet above the level of the sea, and fifteen miles from the coast.

Lanuvium, that is to say Civita Lavinia, though not the celebrated landing-place of the progenitor of the whole Latin race, became in later times of great renown, for here was situated the Temple of Juno Sospita, venerated throughout the empire, to which the Consuls came to sacrifice, so that in later Republican and Imperial times it was more frequented than its more ancient low-lying sister city. It was the birthplace of Antoninus Pius; he, Marcus Aurelius, and Commodus resided in its vicinity, and it was also the birthplace of Roscius. It is now a walled town—formerly a fortress of the Colonna family, whose armorial bearings are to be seen on the walls—most picturesquely situated at the narrow western extremity of the spur or promontory. In the centre of the town there is a charming little piazza, on which there is a fountain falling into an ancient Roman sarcophagus. It is bounded by ruined palaces, and is open on one side, affording a beautiful view of the Campagna bounded by the Volscian hills, on the sides of which Norba, Cori, and other towns can be discerned. In the distance are the Circean promontory, the hills of Terracina, and the sea. I visited this spot some six years ago, with an eye to excavation, and found some most interesting remains of antiquity. Under the walls on the north are ruins of a theatre; one of the vomitories alone has been explored—this was in 1835. Subsequently the fine statue of Claudius, now in the Rotonda of the Vatican, was discovered on this spot. In the same museum stands also the previously discovered statue of Juno Sospita, the tutelary deity of Lanuvium, but of the exact spot in which it was dug up I have hitherto found no record. Juno Sospita is represented in the attitude of a protectress, with a spear and shield. Her head is covered with a goatskin, and her feet have shoes with pointed toes like the fashionable shoes of the present day, but turned up at the points.

Part of the western wall of circumvallation is of a very early period, resembling the walls of Ardea, and therefore may be pronounced to be Etrusco-Latin. Outside the walls to the south-west there is the cella of a temple of small dimensions, now converted into a warehouse. It stands on the edge of the promontory, near a road leading down to the plain, and is bounded by a fine wall of enormous blocks of an earlier period even than the portion of the town wall already mentioned.

North-east of the town there is a gradual ascent to a sort of plateau much higher than the town itself. The plateau, which is covered with vineyards, extends about a quarter of a mile each way. It is bounded by terraces supported by walls of reticulated masonry.

Sir William Gell, the best authority on the topography of the Campagna, assumed that the cella of the temple (the position of which I have just described) was that of the celebrated Temple of Juno. But there are several objections to this opinion. In the first place, we know from ancient writers that the temple was surrounded by a grove. Now the ancient wall bounding the road to the plain—which has still its ancient pavement—is only about 20 feet from the side of the cella, hardly allowing room for a peribolus, much less for a grove. In the second place, drums of columns, which from their dimensions must have belonged to a much more stately edifice—probably to the Temple of Juno—have been found on the north-east side near the terraces.

Thirdly, it is related that in the grove there were the caves of a serpent or dragon guardian, which was waited upon and fed by a

bevy of young ladies, who were devoured by the monster if they were not quite immaculate. Now, on the site of one of the terraces six years ago I found the entrance to a cave, partly filled up with stones. Strange to say, this entrance no longer exists, as the inhabitants have quite covered it over with soil for the purpose of growing their vines, and have converted the precipitous side of the hill into a gentle slope, so that this cave no longer exists, though I certainly saw it, and, moreover, had a little digging done in front of it, not for the purpose of discovering the bones of the young ladies, but in hopes of finding some ex-votos or terra-cottas.

When in Rome this year, it occurred to me that Civita Lavinia would be the most interesting site within a moderate distance of Rome (it is distant 18 or 20 miles) upon which to made excavations. On mentioning my intention to do so to Sir John Savile Lumley, H.B.M.'s ambassador, he most generously offered me his support in money and influence. After I left Rome in May, Sir John continued the excavations, and it is to his artistic skill that I am indebted for most of the sketches that illustrate this paper, and to his spirit of archæological research that I am indebted for the notes which enable me to describe the most recent finds.

My first object in setting to work was to discover the site of the temple, and with that object I commenced digging on the north-east edge of the plateau, when I soon came upon a wall of large tufa blocks, measuring about 4 feet by 3 feet by 2 feet. This wall, of which three courses in height existed, extended about 40 feet in length, and then returned for some 10 or 12 feet at either angle. Beyond these points the blocks seemed to have been removed by the cultivators of the vineyard. Unfortunately, on account of the obstacles thrown in my way by the proprietor, I could not proceed towards the centre of the vineyard. This wall I supposed to be a portion of the temenos wall. Some of my archæological friends consider it to be part of the arx, but as I found inside the wall several small terra-cotta figures and vessels, ex-votos, which are generally found within the precincts of a temple, I think that fact helps to confirm my theory.

A few hundred yards from the edge of the plateau towards the town there were some piers of reticulated work, covered by enormous masses of wall, and as this appeared to be a promising spot we commenced here, after abandoning the peribolus wall. After some weeks of excavation we came upon a series of piers with attached columns of reticulated masonry, which is a mark of first century work. These piers, which measured, roughly speaking, 4 feet each way, were 12 feet apart, placed at regular intervals, and connected by low walls. The plan of the building was that of an open colonnade or arcade, oblong in plan, with central chambers. The whole measured about 113 feet by 41 feet. There was no sign of voussiors or of architraves, so that the superstructure cannot be restored satisfactorily. But several blocks of moulded tufa were found which seemed to have formed the pedestal of a group of sculpture. Near the principal opening there was an enclosed watercourse. From this fact, and from the evidence of a figure of a naiad, surrounded by waves, found in the vicinity, I came to the conclusion that the edifice had been a nymphæum attached to a villa. Above the mass of ruins there was a corridor of reticulated work. This was above ground. After we had been at work a few days and had got down about six feet, to the original level, which, strange to say, had no signs of pavement, we came upon a horse's head rather larger than life-size, of decided Greek character. The nose was broken off, but there were holes for a bronze bit. From my recollection of the horses' heads of the quadriga which we found at Halicarnassus, where two similar heads were found, I concluded that we were on the track of a quadriga. If so, the discovery would be most important, as the quadriga we found at the Mausoleum and which I was enabled to restore from the fragments, was the only one hitherto discovered. A comparison between the style of the horse's head and that of one from Boudroum is conclusive. Two other heads were also found close to the ruins. Subsequently—after I left—the spoke of a chariot wheel turned up. This was a conclusive proof that the quadriga theory was the correct one. An ear which does not fit any one of the heads was lately found, showing that there was a fourth horse, also several fragments of legs, tails, and hoofs. Hitherto the sculpture found has been fragmentary, but this is almost always the case. I have, at various times, witnessed the disinterment of many pieces of sculpture at Halicarnassus, Cnidos, Priene, and at the House of the Vestals at Rome, but have never seen a statue dug up entire. The statue of Mausolus now in the British Museum was in more than fifty pieces, and an arm of Minerva, which I found at Priene, in quite as many fragments, and it was only by the extraordinary skill of the workmen at the British Museum that these were put together in such a satisfactory manner. One of the very few statues found complete is that of Claudius in the Vatican, which was discovered in the theatre of Lanuvium in a recumbent position, with even its nose intact. This is most unusual, as the nose of a statue is generally broken off in its fall, and you may observe in any museum that, as a rule, the noses of statues are restorations.

Sir John S. Lumley took Professor Lanciani to Civita Lavinia, and also to the villa. He was much interested in all he saw there; he considered that we were quite right in supposing

\* A paper read at the annual meeting of the Royal Archæological Institute at Newcastle-on-Tyne.

the Temple of Juno Sospita to be on the summit. He was quite astonished at what we discovered at Magni's vineyard, which, he said, was more remarkable than anything he had found during the seventeen years he has been engaged in excavations, such an *ensemble* belonging to an entire group of statuary decoration being almost unique. So also with regard to the horses, which, did they turn out to belong to a quadriga, would be quite unique. He thought they had an archaic character, and that they might have been copied from an ancient Greek model, and they struck him, as they did us, as resembling those of the Parthenon.

An equally extraordinary find was that of six torsos of Roman warriors clothed in the lorica, sagum, and zona. Four of them were found before I left; the other two, which are still more complete, afterwards. They are evidently of late Roman times, and it is difficult to imagine their connection with the chariot group. I may add that the head of a female divinity, Greek in style, has been found by Sir Savile. This apparently was that of divinity in the chariot. The most likely theory is that the horses and the divinity were either the work of Greek sculptors brought from some other place, or imitations of Greek work by Roman sculptors, and that if the warriors had any connection with the chariot group, they were added at a later period.

I may add that the belly of a horse, with trappings like those on the equestrian statue of Marcus Aurelius on the Capitol, was also found.

It is not quite certain that the figures were equestrian. I think they were not, as the bend of the lambrequins is not sufficiently sharp; but that they did not ride the horses of which we found portions is almost certain, as the spoke of the wheel proves the existence of a chariot. If the remaining parts of the horses and the rest of the quadriga are eventually brought to light, I venture to say this will be the most remarkable discovery of modern times.

The excavations are at present stopped on account of the hot weather and the approaching vintage; but they are to be resumed by Sir John Savile Lumley in October, and I am anxiously waiting for further interesting results.

I may add that we have also in hand an excavation on the site of a villa of the first century near Civita Lavinia, which has hitherto yielded certain fragments of sculpture, which show that we are on good ground. We have found two or three chambers paved with variegated marbles and mosaic, and pieces of sculpture figured of a high style of art.

On beginning we came upon the hypocaust of a bath in complete preservation; but, finding that the superstructure had been disturbed, I moved the men to the edge of a terrace where there were some fragments of porphyry columns, and within the line of the terrace came upon a series of chambers richly paved, within which were fragments of fine sculpture. Hitherto no inscriptions have been brought to light, either at Civita Lavinia or at this villa, that could throw any light upon the date of the buildings. But the villa is commonly known by the name of that of Caligula.

## THE PARIS EXHIBITION OF DECORATIVE ART.

FRANCE has now bestirred herself to serious rivalry with South Kensington, says a correspondent of the *Manchester Guardian*, and the scheme for a great museum of decorative art, with a thorough reorganisation of technical education in connection with it, is taking a more and more definite shape every year. This year the Union Centrale des Arts Décoratifs has just opened its third annual exhibition in the Palais de l'Industrie, after bringing to a successful termination a monstrous lottery scheme for the prosecution of the undertaking, which has put some millions of francs into its coffers, at the expense of the peace of mind of the like number of modest speculators throughout the country. The Union Centrale, in which several other societies with the same object have been merged, is nothing if not comprehensive. Its aim is to found not only a museum but a vast library of decorative art, a course of lectures, competitions between artists and manufacturers, and between the art schools of Paris and the provinces, and finally exhibitions, permanent or temporary, in furtherance of the work. All this represents the national sense of the closeness of the international struggle for supremacy in the markets of the world, and it is almost a direct answer to the challenge of South Kensington, as South Kensington was, in its turn, an answer to the challenge of the French exhibit in 1851. The most remarkable thing about it is that it is in a large measure due to private initiative. The manufacturers seem to see the necessity of acting for themselves. The undertaking will be in the main self-supporting; the promoters will take what they can get in private gifts and in subventions from the State, but they will charge for admission to their museum, as they now charge for admission to the annual exhibitions.

The exhibitions adopt the general scheme of classification already drawn up for the museum. That of the present year is confined to the industries in stone, wood (for construction), earth, and glass. Its forerunners were devoted to metals, tissues, wood

(for furniture), and paper. These are classified in sections of modern work, State industries, and a retrospective collection. The system of object-teaching is applied to every art that admits of it under the conditions of space, &c., in the building. Thus architecture is illustrated in huge models of entire structures, some of which give quite a picturesque appearance to the garden of the palace. There is a considerable show of implements and of machinery—saws, for instance, of all kinds, to work by hand, and saws to work by steam. All the great publishing houses have sent their best technical treatises, and these are being carefully catalogued to form the nucleus of the future library, and a perfect technical bibliography of all the arts. The thoroughness of the scheme is exemplified in the wide application given to the term "industries in wood." This is to include every kind of wooden house—houses on sea as well as houses on land; and the Union hopes equally to count on something in the building of a man-of-war as in the building of a town house or a rustic bower. "Grace of line, perfection of workmanship, the very style of sculptured decoration, have in naval architecture a character of force and harmony which constitutes a grand art." "Rolling" houses come in for their share of attention; and carriage building, both for road and railway, forms part of this gigantic show.

The ceramic section is both actual and retrospective, and in this the managers congratulate themselves on having stolen a march on other countries. They took the lead under Palissy, and, according to their own showing, they have kept it to our day in a second Renaissance of the potter's art.

Their competitions for the year (altogether distinct from the exhibition), one of which provides for a travelling studentship, include in stonework prizes for a monumental chimney suitable for a library, and for work in gem-cutting and the engraving of precious stones. In wood we are to see the best "belfry for a town hall" that native ingenuity can produce, and in earthenware and glass the most tasteful objects that can be fashioned from these materials.

The irresistible conclusion formed from a view of the exhibition as it stands is that France is very serious in this undertaking, and that when she is serious she is hard to beat. Foreign competition seems a folly in view of the marvels of the present and the past in that section of the exhibition devoted to the manufactures of Sèvres. Room after room shows in the order of its development the splendid history of this national institution—from the earliest and often not the least successful beginnings down to the colossal vase commemorative of the last transit of Venus. How can we hope to rival the French in mere delicacy and felicity of artistic invention as displayed in this work—the planet figured as an exquisite female form sailing majestically past the sun god seated on his throne, with one hand before her eyes to shield them from his burning rays. Thousands of objects like this show that high faculty in such work is not an accident, but a law of the French mind, and one hesitates to say in what kind of labour demanding taste in decoration, apart from mechanical skill, they ought not to excel. It is probable that their momentary discomfiture in the industrial contest is due to the fact that mechanical skill now plays a more important part than ever in modern production, and that herein they are not so obviously to the manner born. They do not appear to realise this in its full force, and at present their whole effort, as exhibited in the organisation of the Union Centrale, seems to be devoted to a gilding of the refined gold of their natural aptitude in the purely artistic part of the arts. This, however, would be enough to threaten the empire of South Kensington, and the rise of that institution seems to have been about the most disquieting fact for them since Waterloo.

## THE ROMAN REMAINS IN BEVIS MARKS.

A LETTER from Mr. J. E. Price, F.S.A., the secretary of the London and Middlesex Archæological Society, gives some further information respecting the Roman remains which have been found in Bevis Marks. Mr. Price says the whole of the sculptures taken from Castle Street are carefully preserved pending arrangements necessary, before they can be transferred to the Guildhall Museum. The works are suspended for a short time only, owing to the remainder of the structure yet to be cleared being under the foundations of adjoining houses now in course of removal. When these buildings are gone we propose to complete the work which is already so encouraging. The fine section of the wall which crosses Castle Street has been carefully measured, and all sketches taken prior to the filling in of the excavation—a matter of obvious necessity—in order that the traffic should not be needlessly impeded. This particular section of the wall is of the highest interest because the facing is perfect in every respect, and the treble course of bright red tiles well defined. It is 8 feet from the surface line, and as is usual about 8 feet 6 inches in thickness. The sculptures already found comprise a huge stone sarcophagus, hewn from a single block of oolite, and measuring 7 feet long by 2 feet 4 inches wide; it lay parallel with Castle Street, and, unluckily for us, in a direct line with the "gas main," which had to be suspended in mid-air while the ponderous sepulchre was

removed. There are also numerous massive coping stones, semi-circular in section. One with seatings for the bedding of pedestals, &c. An interesting stone, probably a pilaster cap with a bold centre flower and leafage combined, with some uncertain object, but which is apparently a chair supported by legs in the form of winged lions, &c.; forming the angle is another figure draped and sitting on another form of seat. The whole of this composition, which has yet to be worked out, is remarkably suggestive. Another relic shows a panel having a well-modelled figure of a Cupid or genius in bas-relief; the body holds in one hand a festoon or wreath of fruit leaves, and on which a bird is perched. There are already two fragments of inscriptions, and of which, it is hoped, we may have more when the work is resumed. On a huge block decorated by architectural flutings, &c., is a line with the letters I V I, and beneath another D O; both commence the respective lines, and from the sharpness of the joint where they would be connected with the remainder, the other portion should be near at hand. On another fragment appear letters sharply cut, of good size, and of the best period of Roman works. They read:—

A V I  
N T I C  
R—L X X

In addition, there is a small statue of a male figure, clothed, and in singular costume; the head is at present missing. It somewhat resembles the statuette of Atys, now in the British Museum, but I fancy formerly in Mr. Smith's collection, and, if I remember rightly, found in Bevis Marks. The figure holds in his hands a cup or bowl resting upon the waist; at his right side there stands a large amphora, elegant in form. This figure has yet to be identified. There are also numerous isolated pieces, such as a panther's head, fragments representing heads and limbs of other animals, together with a large number of capitals of columns and other architectural pieces. These remains have evidently been employed as building materials when constructing the line of bastions which are attached to the city wall in this locality. They evidently belong to the same series as did those taken from the two bastions already explored. They were all standing in the reign of Queen Elizabeth, for their positions are well defined upon Aggas's map, belonging to their time. Two have been fully investigated, and I believe this to be a third. Of the first, a fully illustrated and descriptive account was published by our Society, and of the second I possess all requisite plans and sections, together with sketches of the sculptures found. Their illustration has only waited for the Society to be able to afford the necessary expenditure. Of the third, we are now acquiring all information possible. It appears to have been about 25 feet wide, some 12 feet high from the chalk line, which marks the level of the building, and its base is about 4 feet below that of the main wall, from which it projects about 15 feet. That it forms no part of the wall, but was built against it, is shown by the presence of the ironstone plinth which runs behind it, and which is continuous in its course throughout the whole line of wall. It has been suggested that the work in hand might well be undertaken by our local society. No doubt the Council of the London and Middlesex Archaeological Society would gladly endeavour to do what is necessary in such cases could they meet and discuss the question in time; so would also the Council of the Society of Antiquaries, or the Common Council of the City of London; but there is no time to do so, and, therefore it is that we consider that it is advisable for there to be a small executive of working London archaeologists, ready to get at, accustomed to work with each other, and possessing, moreover, the confidence of the general committee, which has the authority to act at once, and who could make additions or fill up vacancies in the executive did occasion require. As an illustration of how far such a matter is beyond the scope of a local society dependent on its annual subscriptions and full of work in hand as is our own, I may add that the expenses of this, the first portion of our work, have already reached just 60*l.*—little enough when compared with the value and interest of the objects found—and when the work is resumed, if I judge correctly, it will have to be continued for some weeks more. Not less than thirty-five loads of rubbish had to be obtained in order to make good the void caused by the extrication of the sculptures.

### THE CARRARA MARBLE QUARRIES.

A REPORT on Italian industries has been prepared by Mr. Beauclerk, of the English Embassy at Rome. The following is the part relating to the Carrara quarries:—

The chief riches of Carrara are derived from the world-renowned marble, of which there are 645 quarries, though only 327 are at present worked. I am happy to note that the odious cruelties to the numerous oxen formerly used in the transport of marble, which have been narrated by so many writers, have now almost entirely ceased, in consequence of the construction of railways from the seaport into the heart of the marmiferous mountains,

In 1879 the total amount of marble brought out of the quarries was 65,841 tons, and there is a yearly increase of the quantity. From 1860 to 1880 the tolls levied on marble by the Commune of Carrara amounted to the sum of 111,792*l.* Over 5,000 men are employed in the works, 3,000 of them working as miners, hewers, and polishers in the quarries themselves; there are 100 studios of sculpture, &c., with over 1,000 workmen; 60 sawmills, with 275 mechanical saws, worked by 350 men; and 22 polishing-wheels, occupying 70 men; whilst 400 others work on marble at the seaport.

The labour of excavation is hard and perilous, the quarries are far from the homes of the workers, and the paths leading to them are often very difficult and dangerous. The men work on the summits of precipitous rocks, exposed to the full heat of the burning sun and to every blast of the violent winds, without any kind of shelter; many of them are suspended by ropes from vertiginous heights. The refraction of the sun from the white marble is well-nigh intolerable, and the atmosphere is impregnated with an impalpable dust, raised by the wind from the continued pulverisation of the roads and material, which is most prejudicial to the health of the labourers. Most of the quarries are at an altitude of from 100 to 200 mètres, and from these heights blocks weighing from 20 to 50 tons are let down by ropes, the men being obliged to accompany them in their descent, which is extremely hazardous, and is rendered the more so by the primitive and careless way in which it is conducted. All the work of cutting out and blasting is done under the most antiquated systems, no modern scientific or mechanical inventions being adopted. The employers are apathetic and niggardly, the workmen foolhardy and ignorant. Hence, numerous accidents occur in every operation.

Children are set to work at a tender age, and hitherto the Government appears to have taken no notice of the whole matter, beyond the collection of taxes. The lower classes of workmen come down to Carrara from the mountains with their wives and families, the latter finding places as domestic servants or begging on the roads. Wages average only 2½ frs. or 3 frs. per day. Nothing is drunk but water, and that often putrid and bad. Breakfast and dinner alike consist only of dry bread with a raw onion or two. Employers pay their men by the week, and make no contract with them for a longer period. In case of a suspension of work from whatsoever cause no compensation is given, and in the event of accidents it is only occasionally that some small present is made to the mutilated and helpless sufferer. Yet the owners make fabulous profits, especially when they hit upon a vein of marble of unusual beauty and value. The hours of work are from 8 a.m. to 4 p.m. in winter, and from 4 a.m. to 1 p.m. in summer; but the distance of the quarries and the excessive fatigue of the work must be taken into account.

The habitations of the workmen are miserable in the extreme. Their children, exhausted by premature labour, grow up dwarfed and lean, and as adults appear pale, meagre, bent, and weak; far different from the Herculean navy whom one would expect to find engaged in such colossal exertions. No education or improvement is even attempted for this unhappy class. Worn out by incessant toil and insufficient food, they abandon themselves on holidays to complete sloth and frequent drunkenness, whence naturally follow crimes of violence and indecency. Thus the miners have become a turbulent and dissolute race, with no ideas of co-operation or fraternity, to whom the friendly societies and similar establishments are of no use or advantage. It is needless to say that Government inspection and supervision are urgently needed to alter such a state of things. The remedies are obvious, and the evil is great.

The quarries of the Massa Mountains are reported to be in even in a worse condition; they are, however, of great importance from the fine quality of their marbles, and their value is daily augmenting. At Serravezza alone the works are better looked after, and the men are paid lower wages in consequence! The annual value of the Carrara marble is estimated at 160,000*l.*; it is exported to every European country, France taking the largest quantity. In Massa there are 200 quarries; the workings were only opened in 1836, and in 1864 the exportation amounted to 10,000 tons, worth 36,000*l.* At Serravezza in 1817 there were only ten quarries; now there are 140, exporting 48,000 tons, worth 48,000*l.* The price of marble varies, not only according to its quality, but rather in proportion to its beauty, and the size of the blocks for purposes of statuary, viz.:—

Cost at the seaport—		£	£
1st quality, from . . .		12	to 64 per sq. mètre.
2nd " . . .		9	12 "
Spotted marble . . .		6	12 "
1st quality, pure white . . .		10	— "
2nd " . . .		7	— "
3rd " . . .		6	— "
1st " veined . . .		10	— "
2nd " . . .		7	— "
Violet-hued marble . . .		14	20 "

Some blocks for sculpture have no fixed value. There is said to be one in the possession of a rich trader at Carrara, for which he asks 2,000*l.*

## NOTES AND COMMENTS.

THE new Institute of Architecture, Science, and Art, in Dundee, has been established, with Mr. JAMES MACLAREN for the first president, and Mr. CHARLES OWER for the honorary secretary. The members are to be engaged professionally in the practice of architecture, the applied sciences, or the fine arts for a period of not less than seven years. There are also associates and honorary members. The entrance fee for members is ros. 6*d.*, and the annual subscription is to be of the same amount. Associates are to pay 5*s.* entrance and 5*s.* yearly. The season is to last from October to June. In addition to the ordinary meetings the members and associates can meet in classes for the study of specific subjects. Prizes will be offered for designs, some being restricted to members and associates, while others are open to residents in the counties of Forfar, Fife, and Perth. The papers which are to be read in the first session are on attractive subjects. Professor BALDWIN BROWN will lecture on "Architectural Art," Mr. PATTULLO on "The Law of Building Contracts," Rev. G. M. SMITH on "Church Bells," Professor CARNELLY on "Chemical Facts connected with Plumber Work," Mr. G. S. AITKEN on "Ecclesiastical Architecture," Professor EWING on "The Sanitary Inspection of Dwelling-houses," and Mr. SPINDLER on "Art Work in the Middle Ages." The Institute begins under good auspices, and it deserves to succeed.

WHEN the penny post was introduced it was proposed to use envelopes on which figures were to be engraved from designs by known artists, and copies of one which was produced by Mr. MULREADY as an experiment are now found in collectors' portfolios. It is needless to say that the plan was not carried out, and a head of the QUEEN engraved on steel was substituted, and was in use for many years. Latterly one cut on wood, and much inferior in style was substituted. It is now proposed to form a committee, who will report on the possibility of introducing stamps of better design and colour. A reform of this kind is essential. The English are about the worst in style among European stamps, and unhappily the example of using inferior work has been imitated in the Colonies. If the English is contrasted with the French postage stamp, it must be concluded that there is a singular absence of designing power in this country.

THE competition for the new municipal buildings at Burnley has been decided in favour of Mr. HENRY HOLTOM, of Dewsbury, on the recommendation of Mr. WATERHOUSE, A.R.A. Mr. HOLTOM is now Mayor of Dewsbury, but in spite of the time claimed by his civic duties, he has been able to succeed in two important competitions in the course of a few months.

THE next award of the prizes in connection with the OWEN JONES Memorial will be made in 1885, when six prizes are offered for competition, each prize to consist of a bound copy of OWEN JONES' "Principles of Design," and the Bronze Medal of the Society of Arts. They are open to "students of the schools of art, who in annual competition produce the best designs for household furniture, carpets, wall-papers and hangings, damasks, chintzes, &c., regulated by the principles laid down by OWEN JONES." The prizes will be awarded on the results of the annual competition of the Science and Art Department. Competing designs must be marked "In competition for the Owen Jones prizes." No candidate who has gained one of the above prizes can again take part in this competition.

DUNFERMLINE, although an ancient town, is not large; but at the last art exhibition 127 pictures were sold, for which 1,611*l.* was received. This is satisfactory to the artists and honourable to so small a town. It is found that 8,650 people paid for admission to the galleries. Although the success of the late exhibition has been so gratifying, the Council have come to the conclusion that, for various reasons, it would not be prudent to attempt to hold one this year; but they hope to make a special effort to secure an equally interesting and valuable collection as soon as practicable.

THE new extension of the Walker Art Gallery in Liverpool will be opened to the public on Monday next, and remain open until December 6. The exhibition this year is unusually

interesting, as, in addition to the usual display of contemporary art, nine galleries will be occupied with representative exhibitions by the leading art societies. There will be works from the Grosvenor Gallery, Royal Society of Painters in Water-Colours, Royal Institute of Painters in Water-Colours, Royal Hibernian Academy, Institute of Painters in Oil-Colours, Dudley Gallery Art Society, Society of Painter-Etchers, Liverpool Academy, all of which will be arranged by artists and officials of the various societies. There will also be a collection of architectural designs, which will be hung by Messrs. ALDRIDGE, KIRBY, and CULSHAW.

THE prehistoric archaeology of Ireland has hardly received the attention it merits. The remains at Newgrange suggest how much must still exist in a county like Meath, which has undergone many transformations. The latest discovery is a beehive house at Tara, the hill on which the general assemblies of the petty kings and chiefs were formerly held. The house is about 10 feet in diameter. The walls are of field stones laid dry, and from 15 to 18 inches thick. There are two openings for entrance. The outer surface was covered with clay. A sort of white mould is upon this clay, and gives it the appearance of having been mixed with lime, but when it is rubbed between the hands the whiteness disappears, and nothing but the clay remains. The action of the heat and light produces a whitish mould on the interior surface of the stones, which gives it the appearance of being lime-washed. Above this clay, which was evidently placed in position by human hands to keep the structure together, there exist several beds of material in undisturbed layers, fine sand, gravel, loosely aggregated gravel, sand, and mould. In an adjoining field the topmost slab of a former habitation was overturned some half century since by a ploughshare, and disclosed a larger compartment of oblong form.

A CURIOUS document relating to St. Mary's Church, Maldon, has been discovered. It is an answer to an appeal to King CHARLES I. for aid towards repairing the building. The inhabitants said they subscribed to the uttermost, but fell short of the required amount by a thousand marks. His Majesty gave authority for the collection, and arranged that "Two Bayliffes and two Justices of that Borough shall give order for the keeping, yssuing, and bestowing of the sayd moneyes and the accompts thereof, that the publique worke intended thereby for reedyfying of the Church may be performed accordingly." This was in 1628, and it is not a little remarkable that at the present time the church is in no less urgent need of repairs, while no money is available to pay for them.

HUNGARIAN industry appears to be showing progressive improvement. It is declared to show prosperity, and to be making energetic efforts to take the position which foreign competition has hitherto maintained. The furniture manufacture, the production of china, majolica, and bronze, are stated to exhibit signs of progress which a few years ago could not possibly have been anticipated. In the building trade Hungary is entirely independent of foreign assistance. The brick trade was very prosperous in 1883 owing to the building activity. No less than 85,000,000 to 90,000,000 bricks were used in Pesth in the course of the year, at from 1*l.* 13*s.* to 1*l.* 16*s.* per 1,000. There are six factories in Hungary employed in the manufacture of furniture and of other articles of bent wood, principally for foreign purchasers. The value of the exports was from 1,500,000 to 2,000,000 florins. The furniture trade in Austria is no less important. Two of the companies established at Vienna employ 8,000 persons in their factories.

THE Luxembourg Galleries have undergone some alteration, and thirty new pictures have been hung—the greater part in the central gallery. An innovation in the sculpture gallery is the appearance of several examples of sculptured gems. Among them are two cameos by M. FRANÇOIS, *Venus rising from the Sea*, and *Andromeda*, and the *Birth of Mercury*, by M. GOULARD. How is it that the art of sculpturing gems is unknown in this country, although so much money is expended every year on foreign examples? The Royal Academy might aid in fostering it if cameos and other sculptured gems were made eligible for admission.

## ILLUSTRATIONS.

DESIGNS FOR THE ADMIRALTY AND WAR OFFICE.

WE publish this week the accepted design by Messrs. LEEMING & LEEMING for the new public offices, and also the design by Messrs. ASTON WEBB & INGRESS BELL. It has been already stated that we have been compelled to delay the publication until we were in a position to produce plates which would faithfully reproduce the originals.

## ANTWERP INTERNATIONAL EXHIBITION.

THE Lords of the Committee of Council on Education have received information through the Foreign Office that the international exhibition at Antwerp will be a national and governmental undertaking, under the immediate patronage of His Majesty the King of the Belgians. The president of the exhibition will be His Royal Highness the Count of Flanders, and the vice-president the Minister of Agriculture, Industry, and Commerce. The committee will consist of 450 members, and the Belgian Parliament will be asked to vote a sum of money for the commission. The State will nominate the jury and regulate its functions. The exhibition will be opened on May 2, 1885, and will embrace five principal divisions or sections, namely:—1. Education, including the fine arts and art applied to industry. 2. Manufactures. 3. Commerce and navigation, fisheries and pisciculture. 4. Electricity. 5. Agriculture and horticulture. Each of which will again be subdivided into groups and classes. The triennial exhibition of painting, sculpture, and architecture, to which artists of all countries will be invited to contribute, will coincide in 1885 with the universal exhibition.

The growing importance and favourable geographical position of Antwerp give every reason to hope that the proposed gathering will be largely attended. No effort will be spared to insure the success of the undertaking and to make it worthy of the attention of foreign nations. All necessary measures will, it is stated, be taken on the part of the Belgian Government to protect all patentable inventions, models, drawings, or trade marks which may figure at the exhibition. An influential committee of citizens of Antwerp, under the honorary presidency of the burgomaster, is now actively engaged in forwarding this vast enterprise in its various branches.

## ART AND LABOUR.

A LECTURE was delivered lately by Mr. William Morris on "Art and Labour" in his own house at Hammersmith. The lecturer said that the subject of the lecture was "What have been, what are, and what should be the relations between art and labour?" By art he meant something wider than was usually meant by the word. He did not mean only pretty ornament, though that was part of art; he did not mean only pictures and sculpture, though they were the highest manifestations of art; he did not mean only splendid or beautiful architecture, though that included a very great deal of all that most deserved to be called art, but he meant all those things and a great many more—music, the drama, poetry, imaginative fiction, and above all and especially the kind of feeling which enabled us to see beauty in the world, and stimulated us to reproduce it, to increase it, to understand it, and to sympathise with those who especially deal with it. In short, by art was meant the intellectual and therefore specially human pleasure of life, distinguished from the animal pleasure, and yet partaking of its nature in many ways, and which pleasure is produced by the labour of men, either manual or mental or both. Now this pleasure he was sure the world could not do without. Nothing could take its place. If they lost that they lost civilisation; nay, all life that was worth living; for surely whatever degradation men might undergo they could never live the innocent life of the beasts, or be happy in such pleasures only. Furthermore, of late years some who most loved art—and he would name his friend and master, Mr. Ruskin, as the most prominent among them—had likewise awakened to a sense of a terrible lack in the life of to-day. They have felt as if this pleasure of life were slipping away from the world, as if something or other were robbing them of it. That decrepitude of art which once only filled them with dismay and hopelessness showed with another face now, and they recognised in it one of the tokens of the coming change in the basis of society which they so ardently desired. All along they had dimly seen that what was called modern commerce, or the reckless war of the market, had been the foe of art or the pleasure of life, and now at last they were beginning to see that the very sickness and confusion of that pleasure was a sign of commercial war wearing itself out, fretting itself away; that the foe itself would at last kill itself, and give place to something better—nothing less than that which they and he called socialism. So, with their eyes thus cleared, they could face modern ugliness and unrest with hope, and accept it and their

own discontent with it as signs of encouragement—nay, as signals for action. Well, what they as lovers of art and defenders of the pleasures of life had learned was really this: that art depended on the labour of the mass of men, and that the commerce of modern times was destructive to art, because it was the oppressor of labour, and by the commerce of modern times they would understand he meant the system of exchange which lived on the exploitation of labour—that system of profit-grinding of which they all formed a part, either as the grinders or the ground. The practical inference they had drawn from all this was that they would do their best to overthrow this system with good hope, in spite of its apparent strength and coherence. Now, as it was by the teaching of history that they had learned this lesson, he asked their patience whilst he briefly ran over the relations of art to labour in past times, that they might have some kind of idea how it was that the comparatively modern monster of profit-grinding gradually sucked art or the pleasure of life into its relentless mill to be ground up fine with many other things, some of which he hoped would come out of the mill in a very different condition from that which the grinders hoped for. To drop metaphor, what he wanted to show them was how the enslavement of the whole mass of workers at the hands of the capital-and-labour system had necessarily involved the gradual sickness of the arts, and would, but for the coming inevitable revolution, entirely destroy them in the course of time. To pass over the conditions of men as mere savages, one came across civilised men in history served by labour under three conditions, chattel slavery, serfdom, and wage-earning, which he described at some length. The life of labour throughout the Middle Ages was a struggle for freedom from the restraint of privilege. That struggle ended in victory. Even in the eighteenth century it was commoner for people to make things ugly than beautiful, and no wonder, for the worker had, as a rule, no longer to think of what he was making, and so could take no pleasure in it. It seemed to him that the second question, "What are the present relations of art to labour?" was soon answered. The relations were simple enough, for labour was wholly divorced from art. As to his work, he was either himself a machine, or was the slave of a machine. There was no art in his work, and as to his life outside his work, he had neither money, leisure, or education, that was refinement, sufficient to obtain it. He greatly feared that some of them would think that this did not matter at all; he was fed, clothed, and lodged in such a way that he made a good workman, for making a profit for other people, and was contented with his lot—as yet. He would risk answering the third question, "What should be the relations between art and labour?" First, the workman must live in a pleasant house in a pleasant place; that was a claim for labour which he knew they would be inclined to agree with until they considered how impossible it was to satisfy it under their present profit-grinding system. They must also think that a pleasant house was and must be a costly house. Second, the workman must be well educated. There again he thought they would agree with his words till they knew what they mean, namely, that all children should be educated, not according to the money their parents happen to possess, but according to their capacity. Less than this meant class education, which was a monstrous oppression of the poor by the rich. Third, the workman must have due leisure. Overwork for profit must be prevented at any cost. The necessary maximum of a day's work must be found out, and made legal and compulsory. It follows as a corollary to this claim that everybody must labour. So much for the necessary surroundings of life under which art for the whole people would be possible. They would see that what these three things really mean was refinement of life, or, as they called it now, the life of a gentleman, and he would tell them quite plainly that if the workers had no hope of becoming refined or gentlemen, they would in the long run become brutes, and those of the well-to-do classes would be no better. Please to think of that and what it means. The lives of some of them might see its terrible meaning explained unless they grew wise in time. Now as to the manner of work if they were to have art among them once more. First, there must be no useless work done. This indeed follows as a matter of course on the limitation of the daily hours of labour, but also of course—he knew they would not agree with him at all in this—as the well-to-do classes mostly live on useless labour, the turning of the wheel of the profit-grinder. Second, whatever necessarily irksome work must be done, should be done by machines, which should be used to save labour really, and not, as now, to grind out profit. He knew that this involved the, to them, monstrous proposition that machines should be their servants not their masters, but he made the claim without blushing. Third, no useless work being done and all irksome labour saved as much as possible by machines made their servants instead of their masters, it would follow as a matter of course that what other work was done, which in truth would be by far the most important part of work, would be accompanied by pleasure in the doing, and would receive praise when done, and most true it was that the product of all work done with pleasure and worthy of praise was art, that was to say an essential part of the pleasure of life; beauty was the necessary expression and token of such work. Of course they would

say this kind of work was desirable doubtless, but impossible to realise; but let him remind them that to a certain extent it was realised in the Middle Ages, when the workman was master of his material, tools, and time. In order to realise the kind of work he had been speaking of, he must once again be master of these things, and this must be brought about, not by reverting to the system of the Middle Ages, which was obviously impossible, but by making him the master of his time, tools, and material, collectively or socially; that was to say that the labourers must regulate labour in the interests of the labourers. He knew that this meant the altering of the basis of society. He doubted not that such a change would be thought a heavy price, indeed, to pay for art even if it be true, as he still asserted that it was, that they could not have art without that change. He had called art the pleasure of life, which, indeed, means nothing short of happiness. Tell him then what was too high a price to buy general happiness with. The re-awakening of socialism, supposed to have been dead, in a new and scientific form, even in England, the stronghold of middle-class supremacy; its rapid spread over the Continent of Europe, and especially in Germany, the land of education, all these things point to the coming of the great change when the time shall be ripe for it. Nor, on the other hand, are there lacking signs of that ripeness. The lecturer concluded by saying that there were even now but two camps, one of the people and one of their masters. Between these two they must make their choice, as they would full surely find before long. Rich and poor were the words which divided the world, and he earnestly begged them to join themselves to the cause of the poor, in the hope that those two names, so long expressive of the curse of the world, should one day have no meaning to them, but that they should all be friends and good fellows united in the communion of hopeful and pleasurable labour which alone could produce art, the pleasure of life.

## FRENCH ARCHITECTURE IN COCHIN CHINA.

A CORRESPONDENT of the *Times*, writing from French Cochin China, describes some of the buildings in the small principalities. The town of Saigon, he says, is well known as one of the most attractive towns in the East, notwithstanding its evil climate. Owing nothing to natural advantages, it rivals Hong Kong and surpasses Singapore, of which the English traveller brings home enthusiastic memories. The buildings of Hong Kong are solid and grand, but French taste beats them out of the field. The roads of Singapore, half-suggestive of the jungle, supply abundance of beautiful drives; but the boulevards of the French town, without losing their tropical character, are prettier. Every house has its garden fence trimly kept. The public offices are spacious without the dreary, warehouse look of most of our Eastern buildings of the kind. Singapore prides itself on its Government House as the finest in the East, but it has not the grand façade of the Palais du Gouvernement. The French are fond of abusing the admiral who built it, and lament the twelve millions it cost; but, if it were destroyed by an earthquake tomorrow, they would build another exactly like it. The *enceinte* of the town is conceived with the ambition which foresees *la nouvelle France* the great Indo-Chinese Empire. Admiral de la Grandière, who laid it out, dreamed that Saigon was to be a town of five million souls, and he marked out the limits with this grand idea in his mind. Time as it rolled on has not fulfilled his hopes. Possibly the dream of the rival empire to British India may be equally ill-based. Saigon does not, indeed, decrease in numbers. There is even a steady increase, but it will be far on in next century before the admiral's skeleton town ceases to appear ridiculous. If the numerous villages which lie between Saigon and the Chinese centre, Cholen, are counted as part of the capital, the total population now rises to about 115,000. But the European town properly so-called (and Saigon is nothing if not European), does not contain more than 30,000 inhabitants. In 1880 Rangoon proper had a population of 134,176, and it is growing by leaps and bounds. The suburban villages of Poozoon-doung and Kemmendine do not leave us much doubt as to whether they should be included or not. They are already on the point of being engulfed, just as London has swallowed up the villages of last century, the Highgates and Chelseas and Kensingtons. But Rangoon is not a beautiful town. There are people whom it is impossible to suspect of preconceived malice who do not hesitate to declare that it is extremely ugly. Government House at Rangoon is fairly water-tight. Beyond that it would be affectation to make any assertions. The only public buildings which make any pretensions at all are the Town Hall, which is quasi-Oriental, a kind of half-caste erection, and on the other side of Fytche Square the new Law Courts, a specimen of Gothic architecture—very early and rather depraved Gothic. There is not a doubt that as far as appearances go our Burmese capital cannot be mentioned in the same day with Saigon. The general object of the average Briton in going to the East is, however, not to make a great show, but to gather together a reasonable sum of money. It comes to the old story, then. We are a nation of shopkeepers.

The correspondent next describes a visit to Pnom Penh, the capital of Cambodia, which is situated at a point of the river called Quatre Bras, a star-fish like place, which adds greatly to its commercial importance. Below the town are the Fleuve Postérieur and the Fleuve Supérieur, and above the Mekong and the Teuli-Sap, running down from the Grand Loi.

The capital is picturesque enough to look at from the outside. The actual town is like all Eastern places, much less attractive. It is the merest passage, little more than a street deep, along the river banks. In the centre of this long strip of town, in a place cleared out for itself, dwells the *personnel* of the French Protectorate. The buildings are all very solidly and attractively built, and everything is made as comfortable as possible, of course, at the expense of the Cambodians. Beyond these, and since the burning down about a month ago of the splendid house belonging to the Hong Kong and Shanghai Banking Corporation, along with a considerable slice of the business part of the town, there are no buildings except of the most ordinary kind. The royal palace is disappointing when compared with those of Siam and Burmah. King Norôdom is a flighty personage, much like the late King of Burmah. Like all children and semi-savages he is fond of new things. The main object of most of the trading people in Pnom Penh is to find out some novelty which will strike the royal fancy. Then they take care to make him pay for it. The French are rather proud of their *protégé*. He is supposed to have acquired a gloss of Parisian civilisation. What amount he has is exceedingly flaky. The palace enclosure is a huge indefinite kind of a space, inside which are a number of residences which His Majesty has built and given up one after the other. There is one which he had built in European fashion from French designs. It is now abandoned, and the key is apparently lost. At any rate, nothing can be seen except a few frescoes and roof paintings, executed in the vestibule by an Englishman named Holland. In front of this is a garden in a dismal state of desolation, with a magnificent bronze fountain, sent from France, the basin empty, the "little wanton boys" being capsized off their bladders, and the whole thing likely to collapse in another season or so. Alongside of this there is the present throne-room, an oblong hall, built in semi-Chinese fashion, with flamboyant pinnacles and lavish gilding. The walls and the panels of a double central line of pillars are covered with fine French mirrors. There is much gilding and tinsel work, especially on the throne at the end of the hall. In the centre are raised places for the most eminent among the Buddhist monks. Numerous chandeliers hang from the roof, which is adorned with mythological designs, painted on cloth sent out from Paris. Alongside of this again is a large, open, pillared hall, which serves as Parliament, law-court, and theatre. There is a sort of permanent stage at one end, and above are hung painted pieces of cardboard to represent clouds. Besides these there is the harem, in which there are three hundred or more wives, and an iron palace in which foreigners are received. This, some may remember, was at the Paris Exhibition, but it has been cut down in size to suit the king's taste for things in miniature. There are then halls, courts, stables, and what-not scattered about, notably a band-stand, where a band of Manila men discourse Offenbach's music to His Majesty when he is tired.

## CRAIGMILLAR CASTLE.

A PARTY of members of the Edinburgh Architectural Association visited Craigmillar Castle in March of the present year. The secretary, when writing to the proprietor, Mr. Little-Gilmour, thanking him for his courtesy, took occasion to mention that parts of the ruin were becoming dangerous, and that it was desirable something should be done to avert the decay. Mr. Gilmour requested the secretary to communicate with the land steward on the subject, and, in consequence, arrangements were made to have the dangerous parts made safe. A large staff of men were started, under the supervision of Mr. Menzies, architect, with the view of removing the rubbish and vegetation (ivy excepted) from the walls and arches; these latter also were ordered to be repaired and covered with concrete, so that water be prevented from finding its way down through them, as in frost the moisture is apt to dislodge the stones. Pointing has been done where necessary throughout the entire building, and the tops of the walls covered with a coating of cement, in order to prevent the rain getting in. On the main roof, which is almost flat, and which has been covered with overlapping stones, a great quantity of earth and rubbish has been removed. It was found that, as few of the overlapping stones were entire, they would only cover a small portion of the roof, and, accordingly, they were carefully laid on the south-west corner in their original position. The remainder of the roof is covered with concrete, with a smooth face of cement on the top of it, sloping down into gutters and carried through the outer wall. A stair in excellent preservation, leading from the great hall down to the west wing, and several other arch-roofed rooms and passages hitherto closed with rubbish are now opened up, and will no doubt be an increased source of pleasure to lovers of ancient architecture. The repairs have necessitated a very considerable expenditure of money, and it is highly creditable to the proprietor that he has

done so much to avert the decay of this magnificent relic of feudalism. Much of the dislodgment of stones and damage to the lower walls and arches is the result of malicious mischief, the ruin being on Sundays a great resort of "city roughs." It is to be hoped, however, that the public will co-operate with the proprietor, and endeavour as far as possible to prevent such disgraceful and lawless proceedings. In removing the rubbish from the top of the arching on the east wing, near the north-east turret, a large stone, on which is carved the Preston arms, in a state of perfect preservation, was found carefully laid face downwards on soft sand, buried six feet deep among the rubbish. It is being built in the wall above the doorway, at the foot of the main staircase. On the top wall of the passage connecting the eastern wing with the main building, part of an iron spear was discovered; while among the rubbish in Queen Mary's bedroom an eye-glass was picked up. The metal round the glass was so thoroughly corroded with rust that it crumbled away between the fingers.

### ANTIQUITIES OF SALONICA.

THE English Vice-Consul at Serres reports that in his district there are ruins of fortresses at Serres, Demir-Hissar, and other places. There are the ruins of a fortress on the top of the hill at the foot of which Serres is built. On the side of a ruined tower belonging to this fortress there is an inscription in Greek, recording that it was the "tower built by Hellen in the mountainous region." A little further off there is the ruin of a Byzantine church, which must have been very beautiful. About thirty years ago there were some frescoes well worth preserving. There is an inscription on a piece of broken marble in the court of the archbishop's palace of a votive decree of the community of Siraion, dating from the Roman occupation. There are also several Greek inscriptions in that part of the Rhodope inhabited by the Pomaks. Ancient coins are found everywhere. Five years ago a coin of the time of Philip was found at Nevrocop, and was sold at Athens for 1,000 frs. There are great numbers of antiquities at Jeni-Kiol, a village of twenty houses, the site of Amphipolis. There are a few remains of a wall on the top of the hill, from which there is a splendid view over the plain and the neighbourhood, which is full of ancient reminiscences. The plough has passed over everything, and the rain has disinterred statues, trunks of statues, and bas-reliefs belonging to the best period of Greek art, jewellery of exquisite workmanship, and abundance of coins of copper, silver, and gold. All these discoveries have been sent abroad. However, there are still some remains of antiquities on the same site, and excavations would have very satisfactory results.

Among the mosques worthy of mention are those of "Eski-Djami" and "Ahmet Pasha." The Eski-Djami, in the centre of the town, is richly endowed and has many revenues. Ahmet Pasha mosque, also called "Aghia Sophia," is situated outside the town, and is built of marble, yellow with age, and is of a simple and elegant architecture. This mosque deserved a better fate, but it now has no funds, as its revenues were derived from the Crimea. The complete ruin, however, of this monumental building is owing to the carelessness of the Mussulmen of Serres. The dome has been stripped of its lead covering, and the mosque is being gradually buried by the layers of sand brought down by a torrent which has been allowed to flow in its direction. Even the old plane trees which existed in its enclosure have not been spared. The Greek cathedral, which suffered greatly from the terrible fire in 1879, has been restored. It has still its ancient form, as the walls and arches suffered very little, but there are no traces left of its splendid mosaics and wood carvings. The "Bezesten" of Serres is an ancient building consisting of four vaults, which are in need of repairs, but no one troubles himself about it.

### WATER-SUPPLY FOR FIRE EXTINCTION IN THE METROPOLIS.\*

IN London the whole of the water-supply is pumped, and the average pressure is quite inadequate for fire extinction without the intervention of fire-engines. A large number of observations were made all over the metropolitan area by the Board of Works in 1876, and it was found that the average pressure was only about 30 lbs. per square inch, when there was no extraordinary draught on the pipes, such as that required for fire extinction. And it is not surprising that this should be so. The pressure given by the water companies is that required by statute, or, otherwise, by the customers of the companies, and even if they desired to do so it might be doubted whether, in the words of the Select Committee of 1876-7, the companies would be "justified by their constitution in incurring expenditure for fire purposes," for which purposes alone would it be necessary for them to increase their pressure.

The quantity of water delivered for all purposes is sufficient to

meet the demands for fire extinction. There are, according to Captain Shaw's reports, very few cases of short supply, and constant supply is being gradually extended voluntarily by the water companies. Hydrants have been put down by the Corporation throughout the City, and connected directly by branches with the constantly-charged mains of the New River Company, and they have on several occasions been found useful, though the pressure is not such as to admit of fire-engines being dispensed with in all cases. A few hydrants have also been recently introduced by the Metropolitan Board of Works in other parts of the metropolis. In the matter of pressure, however, the general metropolitan water-supply is undeniably deficient. There is a copious supply of water, in close proximity to the property to be protected, but it cannot be brought to bear upon a fire without the intervention of fire-engines.

The population of the metropolis in 1881 was 3,814,571, and the Metropolitan Board of Works area is about 121 square miles, including the City's one square mile. There are 55 land fire stations, 12 street, 127 fire-escape, and 4 floating stations; and the brigade consists of 588 officers and men. The annual average cost of the fire brigade for the three years 1880-2, was 99,880*l.*, or 26*l.* 4*s.* per 1,000 of the population. It is somewhat difficult to arrive at the value of the property destroyed by fire in the metropolis, but a calculation based upon the contributions of the insurance companies to the support of the fire brigade, and upon evidence given by Captain Shaw and others before the Select Committee on the Fire Brigade, in 1877, would make it appear that in 1882 the value of insured and uninsured property destroyed by fire was probably considerably in excess of 2½ millions sterling, or about 588*l.* per 1,000 of the population. As compared with efficiently hydranted places, the cost of the fire-extinguishing service, and the fire losses, are very high in London.

It will be asked why the metropolis should have been allowed to remain year after year subject to the preventable drain of wealth indicated by these figures. The reply is that the past and existing state of things have not been submitted to in ignorance or willingly, but the difficulties surrounding the subject in the metropolis have been practically insurmountable.

More than twenty years ago the Select Committee on Fires in the Metropolis directed attention to the extraordinary facilities for extinguishing fires then existing in Liverpool, Manchester, and Glasgow, and to the efficiency and small cost of the fire services in those places; and more recently, in 1876-7, the Select Committee on the Metropolitan Fire Brigade, having heard evidence as to the advantages of the hydrant systems referred to, recommended that hydrants should be put down in the metropolis at once wherever a constant supply was given, and that the water supply should be improved so as to give constant service everywhere, and increased pressure. But it was found that to comply with these recommendations a permanent expenditure of 337,000*l.* per annum beyond the cost of the fire brigade would be involved. Of this annual sum about 150,000*l.* represented the increased cost of pumping alone; and since the quantity of water required for fire purposes is infinitesimal as compared with the quantity supplied for all other purposes, it is obvious that this expenditure of power, if the whole had to be pumped to the requisite height, would be out of proportion to the result obtained. I have made a calculation, based upon the relative quantities, and upon the evidence given before the committee, from which it appears that for the purpose of discharging water through a hydrant upon a fire in this way, about 170 horse-power would be required for every gallon of water thrown. And there would be the attendant disadvantages that all the house fittings would have to be altered and strengthened, and the mains and pipes would have to be taken up, and relaid of greater size and strength, and at enormous inconvenience to the householders and the traffic in the streets; and the pressure would, in the greater part of the metropolitan area, be inconveniently great. This proposal also involved the great disadvantage that it could not be carried out until the water companies should have been ranged under one control.

As long ago as 1862, the late Mr. James Easton, who held the view that no satisfactory supply of water for fire extinction with constant high pressure could be secured in connection with the ordinary domestic supply, proposed to lay down a completely new set of mains to be used exclusively for fire purposes, but the cost would have been enormous. His estimate was 72,000*l.* per square mile, and his proposal only extended to 40 square miles of the metropolis. This area alone would have involved an annual cost for interest and working expenses of 150,000*l.* A somewhat similar proposal, but with the addition that the water was to be taken from the chalk formation at about 15 or 20 miles from the centre of London, instead of from the water companies' mains, as was proposed by Mr. Easton, and that the supply was to be used for potable and culinary purposes after being pumped to the greatest attainable elevation in order that it might have sufficient pressure for fire extinction purposes, was put forward by the Metropolitan Board of Works, on the advice of Sir J. Bazalgette, Sir F. Bramwell, and Mr. Edward Easton, in 1877. It was estimated that the introduction of this system of hydrants would have resulted in an annual saving of 60,000*l.* in the existing expenses of the fire brigade. This scheme, involving a dual supply to every

\* From a paper by Mr. J. H. Greathead, read at a conference at the Health Exhibition.

house, was taken to Parliament, but was withdrawn; and in their annual report of 1878, the Board said that they "came to the conclusion, in view of the disfavour with which the scheme appeared to be regarded by most of the local authorities of the metropolis and others, not to bring it before Parliament again in the following session." Looked at purely from a fire extinction point of view there is one great objection to all the proposals that have been hitherto made, viz., that owing to the great variations of level in the metropolis, there would, in many localities, be insufficient pressure, while in others the pressure would be excessive.

In any water supply for fire purposes, it is certainly desirable that the pressure, in addition to being sufficient, should also be moderately uniform in the hose, whatever may be the elevation of the locality. This uniformity is practically obtained at present by the use of fire-engines, but with the great drawback that the power requisite for giving the pressure is not available on the instant that the occasion for its use is discovered. Since the year 1870, when Captain Shaw first began to publish the distances travelled by his engines, the distances run have increased from 11 miles to 34½ miles (in 1882) per fire. The number of journeys made has increased from 8,000 to 29,000, and the total distances run from 22,000 miles to 66,000 miles in the year. According to the evidence given before Sir H. Selwyn Ibbetson's Committee in 1877, the fire-engines were then only used for pumping at about one-fifth of the fires. If that was still the case in 1882, then it follows that for each time the engines were used for pumping upon a fire they must have run on an average 172 miles.

When it is considered under what unfavourable conditions, and how uselessly the journeys are often made, some idea may be formed of the superiority of a system of hydrants where the power as well as the water is always on the spot ready for instant application. The growth of the cost of the fire brigade service, from the commencement of the old fire-engine establishment in 1833, has been and is very rapid as compared with the growth of the population. In the first year of the Metropolitan Board of Works' administration of it, the cost of the brigade was under 41,000*l.*; in 1882 it was 106,552*l.*, or an increase in the period of sixteen years of 160 per cent., while the population increased only 28 per cent., and the number of fires 44 per cent. And in the year 1883, the cost had further increased to over 115,000*l.* It must not be supposed for a moment that this increase is to be regarded as unnecessary under existing conditions. The cost of the London Fire Brigade is, thanks to Captain Shaw's admirable organisation, still small as compared with some other unhydranted cities. In New York, as already stated, the cost is very much greater for less than a third the population and area. There the average annual cost for the three years, 1880-3, was over 288,000*l.*, and it appears to be growing almost as rapidly as that of London, though on the other hand the population there is growing more rapidly. Paris, also another practically unhydranted city with half the population, spends proportionately more than London for fire extinction.

### ITALIAN IRONWORKS.

THE Ironworks of San Giovanni in Val d'Arno were first established in 1872. The company promoting the enterprise was unsuccessful, owing, it is said, to the inferior quality of the products, and in 1880 the works were taken over by the Società delle Ferriere Italiane, by which they are profitably conducted. The official domicile of the company is in Rome, the board of management at Florence. The nominal capital is 4,000,000 lire, of which 2,000,000 lire are paid up. In addition to the works of San Giovanni and the neighbouring mine of lignite, the company holds the iron works of Mamiano, and on lease those of Tarquinia Corneto, district of Civita Vecchia. The total gross receipts of the company in 1882 amounted to 328,646 lire 29 c., the expenses to 213,089 lire 57 c., showing a net profit of 115,606 lire 72 c.

Great improvements have been introduced within the last two years at the works of San Giovanni. New buildings and machinery have been added, and the monthly output has been raised from about 800 tons to 1,400 tons. The gross receipts for the works rose from 87,000 lire in 1881 to 147,000 lire in 1882. Attention is now being particularly given to the production of puddled iron; special articles, such as rolled joists (*travetti*), are also being made, and a contract has been concluded with the "Impresa Industriale Italiana di Costruzioni Metalliche of Turin," which, by insuring a regular sale, enables the company to undertake the production of tee, angle, and other iron bars of various qualities, which up to the present time had generally to be imported from abroad. The total number of hands employed at the works of San Giovanni is about six hundred. The workmen are all Tuscans, many coming from the neighbourhood of Pistoja. The foremen at the furnaces are paid 7 lire per diem; the hands receive, on the descending scale, 5 lire, 3 lire, 2 lire, and boys 1 lira 50 c. per diem. Twenty-five Italian lire are about equal to an English pound sterling.

The works contain six heating furnaces, three puddling furnaces on the Siemens gas system, four rolling mills, &c. The engines set up at the works are from Stuttgart, with a total of 400 horse-

power. The iron driving-wheel, made at Treviso, is 6.50 mètres in diameter. The rollers were constructed in England by Akrell, of West Bromwich; the steam hammers (three) by Massey, of Manchester. Old and broken iron is used for ordinary qualities of iron bars; for the finer kinds pig iron, made from Elba ore, melted at Follonica and by Messrs. Tardy of Vada, is employed; English pig iron from Middlesbrough is also used. The only difficulty in the way of the more extended use of English iron is the elevated railway tariff of 6 cents. per kilomètre and the difficulties of landing at Leghorn, so that the white pig iron of Middlesbrough, which costs 62 lire on board at Leghorn, has to pay, in addition, 9 lire 50 c. per ton for carriage to be delivered at San Giovanni.

### MANUFACTURE OF ASPHALTE.

AN English firm, Messrs. H. & A. B. Aveline & Co., some years ago established asphalté works in Catania, which have made great progress. They are the only works of the kind in Sicily, and employ a large number of men. Forty tons of prepared asphalté can be produced every day. The mines are situated in Ragusa, and the asphalté being analysed is found to be a pure carbonate of lime, with about 9 per cent. of bitumen and of rock, and, owing to its natural hardness, presents the most suitable qualities for making roads in compressed asphalté. Messrs. Aveline have laid their asphalté officially in Berlin, and the results far exceed their expectations, because it has turned out superior to all other qualities there laid. The position of their works is such as to enable them to ship to most countries at lower prices than the mineral coming from other sources, and thus puts this article in a position to compete with many kinds of pavements which up to now have been used on account of their being relatively cheaper. Messrs. Aveline's mastic in blocks has been admitted by the Italian Ministry of Industry and Commerce for use in many works in Government departments in Italy; its richness and elasticity is highly prized, and as their mastic is made of pure rock and bitumen, it is of great durability and unaffected by changes of temperature. Each block weighs from 57 to 60 lbs.

### THE INTERNATIONAL HEALTH EXHIBITION AT SOUTH KENSINGTON.

THE tendency at the present time is to convert the Health Exhibition into a place of amusement; and it must be acknowledged that the majority of the visitors think more of the attractions in the gardens than of the objects to which the exhibition owes its existence. How far the authorities are responsible for arrangements by which the utility of the exhibition is minimised we need not now inquire; but if the exhibitors are heard grumbling at their position they have reason on their side. Under the circumstances, it is the duty of the press to call attention to the contents of the stands which contain sanitary appliances, as they are likely to be disregarded for the sake of things of a different nature; and accordingly we offer our readers a further instalment of notes on the exhibition.

Mr. W. White.

At No. 830, Mr. W. WHITE, Abergavenny, is showing his "Hygeian Rock" building composition. The valuable properties of this patent have been reverted to upon several occasions in *The Architect*, and at the Stand it is to be seen in its various applications. For strengthening walls, 9 inches of brickwork built with it will bear the same strain as 18 inches set in mortar; for damp-proof courses, and for building brick cisterns, it is not surpassed; for providing a cure for existing damp or wet walls it is also well adapted. Its properties for imparting strength to brickwork when built up with it are clearly demonstrated in the following manner: a block of brickwork 9 inches thick, 4 courses deep, rests on supports with bearings of but a few inches, though with a span of 5 feet 6 inches. Around this is passed a chain, to which are suspended several heavy weights. Upon close examination the secret of this extraordinary strength will be found in a flitch of the composition that has been run between the two (4½ inch) walls, and which binds them together. As a further proof of the immense strain it will bear, we recently witnessed a very severe test, when weights to the amount of 1 ton 9 cwt. 3 qrs. were suspended under similar circumstances to above, without making even any deflection, much less to break the mass. Such evidence requires no comment, and we have only to add it still continues to hold quite a unique position, and is the most remarkable exhibit of its kind in this section.

Messrs. Quirk, Barton & Co.

The pure tin-lined lead pipe shown at Stand 642 by Messrs. QUIRK, BARTON & CO., of Gracechurch Street, E.C., has been adverted to in the columns of *The Architect* on previous occasions. When we consider the universally admitted dangers attaching to lead pipe as a medium through which to carry any liquid we are

destined to drink, too much cannot be said in favour of this piping. There is no metal purer than tin. As from its ductility lead pipe is the one exclusively used for alcoholic liquors and extensively for water, it would be highly advantageous if it were made compulsory for all piping used for such purposes to be lined with tin.

*Messrs. Rosser & Russell.*

At Stand No. 509, in the east quadrant, Messrs. ROSSER & RUSSELL, of Charing Cross, are showing their cooking and warming apparatus, and at No. 1,180, in the western gallery, their patent ventilators and chimney-cowls are to be seen. The prominent feature at the former stand is a handsome cooking-range of large dimensions, constructed on their widely-known principles, and fitted with the latest improvements, including arrangements for raising the fire to the hot plate when only a small one is required, and for thorough ventilation of the ovens. The advantages it possesses are of no mean order, and both for strength and durability and ingenuity of construction it is not surpassed by any other in this class, and maintains the reputation the firm have justly gained. Another very important exhibit to be seen here is a newly-constructed portable range, of which the appended cut is a representation. It has received the appellation

of "The Perfect," and letters patent have been granted it. Perhaps the most novel point to be noted is that no matter how large a fire is kept up, there is no fear of anything in the oven being burned. This desirable result is obtained by warming the oven with superheated water conveyed around it by pipes from the adjacent fire, the bars of which are tubular. As we have mentioned it is quite new, though Messrs. Rosser & Russell have put it through severe tests, when it has so fully met their expectations that they are now applying the principle to full-sized ranges, and we hope shortly to be enabled to give particulars of them. The patent ventilators they are also showing answer their purpose admirably, which is that of cleansing or straining the air before it enters an apartment. This is a feature too often lost sight of, especially in close and crowded buildings where the so-called fresh air admitted through an ordinary ventilator is but little better than that it is desired to replace. The extract ventilators and chimney-cowl also possess distinctive points, and are well worth attention.

*The Sanitas Company.*

At No. 554 east annexe, the SANITAS COMPANY, LIMITED, Three Colt Lane, Bethnal Green, have a stand containing the various articles into which this valuable preparation is introduced. We need not enter into a detailed description of what Sanitas is, beyond remarking that it is a product obtained by ingenious manipulation from the eucalyptus tree. As a disinfectant it ranks high in medical and public estimation, and it is perhaps the only one which if taken internally by chance would not be dangerous. Neither should it be destructive to any substances to which it may be applied, and another important feature in its favour is that its smell is by no means offensive, which cannot be said of many disinfectants. Its uses are now so multiform that were we to describe them each at length, they would require a small pamphlet. As a disinfecting fluid, it may be used for a variety of purposes, including clothes, carpets, &c., spraying the atmosphere, and sprinkling floors, as a mouth and tooth wash, for preserving beer, as well as for water-closets, &c. It is also made as an emulsion for washing animals, including domestic pets, and for curing their skin diseases, for deodorising and disinfecting the contents of ashbins, &c., and for deodorising bilge water on shipboard. The "Sanitas" disinfecting oil has been found a valuable agent in the hospital, as a surgical antiseptic dressing, for fumigating the wards, infected rooms, &c., for dressing burns and wounds, and for the treatment of all lung and throat complaints by inhalation, especially diphtheria, in which it has been found of great assistance. Another

form in which it is introduced is as a disinfecting powder, and in this it takes the place of carbolic acid. Turning to the toilet, we find it as a tooth powder, toilet powder, and toilet liquid, and in soaps it is made as a fine toilet, household, and soft soap, which we can recommend from actual use. It is needless to enumerate further preparations or uses, as enough has been said to show its universal value as a cleanser and a disinfectant.

*Messrs. Walter Neilson & Co.*

At 598 in the same quadrant will be found the "Sine Quâ Non" kitchener, exhibited by Messrs. WALTER NEILSON & CO., Park Foundry, Glasgow, and 175 Upper Thames Street, E.C. As this range is in action daily, the visitor can soon make himself acquainted with its salient points. In all respects a "kitchenier," it is made to be used either with closed or open fire, and the ease with which the change is effected forms one of the points of contrast between it and others made to work with the fire open or shut up. A draught-regulating door is fitted in the open flue, which regulates the draught as may be required, and is the means of saving a considerable quantity of fuel. A telescopic flue or hood resting on the edge of the hot plate on either side of the fire is placed there for drawing over the fire, which insures a perfect draught, and will be found very useful in the case of a smoky chimney. This hood can be pushed quite back, if not required. The heat to the ovens is so regulated that it is the same at top as at bottom, and this advantage must soon be recognised by any person who purchases one in the difference visible in pastry baked in this oven. An important advantage claimed for this range is that it is to a large extent a non-smoke producer, which is accomplished by using Shaw's patent smoke abatement grating, a simple arrangement by which the hydro-carbons are so mixed with the heated oxygen as to be mainly converted into flame. The "Sine Quâ Non" kitchenier is made in two ways, one in which it would require to be built in with brick flues in the ordinary manner, and the other, with iron flues, which obviates the "setting" altogether, as it merely requires to be placed in the opening under the chimney. Made in this way it is certainly a tenant's fixture, and it will be seen, easily removed in the event of change of occupancy. A few minutes spent in looking at this range will not be thrown away.

*Messrs. Newton, Chambers & Co.*

In the east quadrant, at No. 596, Messrs. NEWTON, CHAMBERS & CO., of the Thorncliffe Ironworks, near Sheffield, and Great George Street, Westminster, have a fine set of cooking apparatus suitable for a public institution, club-house, or large mansion, and specimens also of their "Thorncliffe Range" in smaller sizes; and a new one of almost diminutive dimensions called the "Economist," suitable for artisans' use or for cottages, a complete *multum in parvo*, doing a great amount of work with a consumption of only 2 lbs. of coal per hour. The large working apparatus consists of a Thorncliffe kitchenier, as illustrated. The boiler of

this range, an ordinary circulating bath boiler, is supplying steam to a steam-cooking apparatus adjoining. A steampipe, attached to the top of the boiler, is carried behind the steaming apparatus, and fitted with four valves: one is attached to a tin steamer for fish or joints, the next to a copper steamer containing four kettles, a third is connected with a 25-gallon jacketed boiler for coffee, tea, or soup, and the fourth to a hot closet, measuring 3 feet 6 inches by 2 feet 6 inches by 1 foot 8 inches; thus the 12-inch fire of the kitchenier is supplying heating power for all these appliances, measuring 11 feet long, and embracing, besides the kitchenier, as illustrated, which contains two ovens, two hot closets, wrought-iron boiler and hot plate, a steaming apparatus with two large steam-kettles, a 25-gallon boiler, steam-closet, and another hot plate, the consumption of coal when in full work being only about seven pounds per hour. Notwithstanding all the new ones that have been introduced, Yorkshire pattern ranges still hold their ground extensively in the North of England. The improvements, however, made by this firm, while retaining the old features in the main, have added to their effectiveness. One of the special advantages claimed for the "Thorncliffe" is that by the peculiar arrangement of the flues the heat ascends much slower, consequently more is got out of the fuel; or, in other words, heat that in many ranges is allowed to pass away without giving off its full caloric, is here arrested in its progress, and its full

power obtained. The fire-doors of these ranges are made to admit a large volume of heated air, which not only promotes combustion but tends to the reduction of smoke.

*Mr. Henry Thompson.*

This gentleman, of 29 Marquess Road, Canonbury, to whom we called attention in a previous report of the Health Exhibition in connection with an open-fire domestic grate, in which the fuel is "coked" in a chamber at the back, and allowed to fall automatically to the front portion of the fire at the bottom, has since the opening of the exhibition perfected his arrangement in such a manner as to make it applicable to a kitchen range. We append an illustration of the range in elevation and section. The former

differs in no wise from any ordinary kitchener, the only difference at all in it being the addition of Mr. Thompson's patent coking-box and apparatus at the back of fire. As our description of the sitting-room grate must be fresh in the minds of most of our readers, we need only now say that the arrangement here is exactly similar. The fuel is coked in the chamber at back; the hydro-carbons pass through a grating behind down into a highly-heated chamber, where, mixing with a copious supply of oxygen at a high temperature, the whole passes upwards through the fire and is almost entirely consumed, the merest shade of smoke only being visible at any time from Mr. Thompson's smoke-pipes. In adapting his invention to kitchen ranges, Mr. Thompson has struck at one of the principal roots of the smoke nuisance, for we well know that kitcheners have hitherto presented one of the most difficult objects of attack to the "smoke sanitarian," if we may be permitted to use such a term. Indeed, Mr. Thompson's invention is so simple that it may be easily adapted to most existing kitchen ranges without unsettling, and the saving of fuel, besides the "saving" of smoke, would soon be very perceptible to the owner.

*The Sanitary Engineering and Ventilating Co.*

In the vestibule at No. 1,010, the SANITARY ENGINEERING AND VENTILATING CO., 116 Victoria Street, S.W., exhibit several diagrams which should interest the householder. They consist of improved self-cleansing cisterns and cistern filters, aerating silicated carbon filters, air-cleansing arrangements in connection with inlet ventilators, and a book, which will be found in the library, and that may be read with interest, named "Sanitary Science and Practice."

*Messrs. Udal & Co.*

At 701 Messrs. UDAL & CO., of Birmingham and Charterhouse Street, E.C., are showing Bruce's patent fanlight and casement opener. A substantially-built working model of a conservatory, with the arrangement fitted to the side and roof-lights, demonstrates in the clearest manner its simple and efficient action, and which, having been described on previous occasions in the columns of *The Architect*, leaves little more to be said of it. We may, however, mention that it dispenses with cords and springs, combines an effective fastener and opener, is self-locking, and applicable for doors as well as for all kinds of window casements, louvres, ship-posts, &c., and by it a heavy or light sash can be manipulated with equal facility. As we have said, it is actuated entirely by levers, one determining the movements of the whole, and the window or casement can be set at any angle by simply turning a thumb screw. It is also suitable for dome top fan-lights, the only additional means here used being a cogged quadrant and rack. Another salient feature is the small amount of working space required. The opener is adapted alike for public or private buildings.

*Messrs. Houghton & Co.*

At Stand 471 is an interesting exhibit, contributed by Messrs HOUGHTON & CO., of Sloane Terrace, S.W. The articles shown are of an original character, though some of them have been before the profession long enough to give them a reliable character. These are the patent fat interceptor, made in various sizes, an improved gully for baths, waste sinks and surface drains, and a good stable gully. There is, perhaps, no greater nuisance to deal with (particularly in the case of hotels, restaurants, &c.), than fat, and an appliance that will collect this before it reaches the drains in an effectual manner is by no means to be despised. So well has Mr. Houghton's fat interceptor accomplished its purpose, that we have seen it incorporated in what have been called model systems of drainage by sanitary engineers in different parts of the country. The firm also exhibit several specimens of faulty plumbers' work, collected from different places where they have been called in to rectify nuisances; and did we not know how irregular sanitary work has in years gone by been carried on, we should feel surprised at what is here shown, but seeing that the plumber of bygone days in too many instances possessed neither practical knowledge nor conscience, we can only pass them by as things of the past, and hope for better results in the future.

*Jaffrey's Patent Grate Company.*

In the east quadrant, No. 438, JAFFREY'S PATENT GRATE COMPANY, 6 Charing Cross, exhibit the open-fire domestic grate known by this title. This grate, made on smoke-consuming principles, was fully described in *The Architect* in connection with the Building Exhibition held at the Agricultural Hall in April last, shortly after its introduction into London. It is shown in action here, and a better or clearer fire we could not wish to see. Our illustration depicts a flat-fronted grate, but they are made "re-

cessed," and with various kinds of ornamentation such as tiles, &c. Since our last remarks upon the Jaffrey grate, several of them have been supplied to public schools and hospitals, and with hot-air chambers at back and sides, one arrangement that has been carried out for a hospital being rather different from that usually adopted for supplying fresh warmed air to a room. In all cases the grate is made with a cast-iron back and sides, leaving sufficient space for a good-sized air-heating chamber. A series of gills are cast upon this casing to arrest the progress of the air (which is introduced from the outer atmosphere at the bottom) in its upward course, and so accumulate heat ere it leaves the discharge aperture. The back gills are fixed at a slight inclination to carry the air more freely to the side chambers, and, on reaching the top, it passes out by a 4-inch opening, and in the new arrangement a stoneware pipe is used which has been let into the brickwork of the wall, and carried to a point adjoining the window, where it escapes into the room by a perforated opening or ventilator. The idea for this "new departure" is that as windows lower the temperature of an apartment both by means of the glass and the

nooks and crannies in the woodwork, draughts are admitted, but by carrying the warmed air as near as possible to these, their temperature is raised at the moment of ingress, and the draughts considerably counteracted. The suggestion is by no means a bad one, and, where new houses are being built, the arrangement may be carried out without difficulty.

#### *The Blackman Air-Propeller.*

Amongst the machinery in motion in the western gallery, and assisting materially to lower the temperature of the surrounding space, will be found the BLACKMAN AIR-PROPELLER COMPANY, whose show-rooms are in Fore Street, E.C. We have described this invention on a previous occasion, but as it appears to be attracting considerable attention and to be in increasing demand, we offer no apology for reverting to it again. Although a means for providing a large amount of ventilation in a certain manner, it is not a "system" of ventilation according to the ordinary acceptance. It is an appliance for keeping in circulation large bodies of air, and will either admit fresh, or withdraw vitiated air in large quantities. It is specially adapted for manufactories, mines, &c., where the air of the places requires to be constantly changed. Although it requires to be worked by power, a very small motor will effect a great amount of work. It is, as our illustration shows,

simply a fan, the blades of which are so shaped that according to the manner in which it is fixed, that is to say, inwards or outwards, so it extracts or brings in air, and herein lies the secret of its success and capabilities. It will be found an invaluable article in factories where the work carried on causes large bodies of dust or "fluff" to arise, to the injury of the workpeople employed; but although mainly introduced for such purposes, we can see many other uses to which it may be advantageously employed, for its worth does not entirely consist in the rapid change of atmosphere. If worked at a less advanced speed it may be used with success in public rooms, &c., and with one arranged to let in fresh air and another to carry off the vitiated, good results may be obtained at a small expenditure of power, and we see no reason why the propeller should not be made of smaller diameter to meet the requirements of theatres or smaller rooms in which entertainments are carried.

#### **The Coming Renaissance.**

SIR,—In your article last week on "The Coming Renaissance," you ask pertinently, "What is the coming Renaissance to be?" Pray allow me to offer briefly an answer to this pregnant question. It has often been urged apologetically on behalf of architecture, that not being an imitative art in direct communion with nature, it cannot prove itself by the test to which the sister arts can always appeal. This plea is but half justified. It gives no valid reason why architecture has in recent times been so helplessly the sport of every fashion in practical antiquarianism. In literature, painting, music, or sculpture, such homage at the shrine of mimicry would have been intolerable. Imagine, *e.g.*, "Pickwick" written in the language of Chaucer! The absurdity of the idea is apparent at its mention; yet architecture for the past 40 years has been practised on such terms, and on such grounds called an art.

The Renaissance of the eighteenth century knew nothing of men such as Pugin, Viollet le Duc, Baron Leys, or Thorwaldsen, whose names suggest nothing more than the study of echoes.

Architecture can, if it will, always know its own position in the

art. This by the greater or lesser degree of its concord with contemporaneous painting and sculpture, and through them only its vital relations with nature.

The coming Renaissance in architecture will be that phase of it which is most modern and which most discourages antiquarianism, in favour of modern painting and sculpture in their latest and highest advancement; in other words, we may take our lesson from the harmony of the arts in France at the present day, where antiquarianism is practically unknown.

I am, Sir, your obedient servant,

Δ

#### **REVIEWS.**

EARTHY AND OTHER MINERALS AND MINING. By D. C. DAVIES, F.G.S. Crosby Lockwood & Co.

There are few sciences which are less popular than mineralogy. One reason is the difficulty of finding opportunities for study. Even in the metropolis the public collections were not accessible to the student until quite recently. The second difficulty arises from the classification. There is no recognised system, and every author can invent a nomenclature of his own. Hence many students lose much time in learning and unlearning catalogues of dry names, and they become disheartened. Mr. Davies follows Dana's arrangement, which somehow finds more acceptance in England than elsewhere, but of course introducing those minerals which have been lately discovered. He looks at the subject from the miners' point of view, and has nothing to say about faces and angles, which to a scientific mineralogist are of more interest than the practical uses of a crystal. Mineralogy is widely related, and a book on the subject must give as much attention to jewels as to building stones. Mr. Davies is comprehensive in his treatment, and, in consequence, there is more in his book which an architect and a builder can utilise than might be inferred from the title. The author has had experience in quarrying, and lately opened a quarry of very tough slate rock in Montgomeryshire, which is to be used in the construction of the new Liverpool water-works. As the minerals that have been utilised in Europe, Asia, and America are described the book may be said to have universal interest, and no colonist should be without a copy.

TEXT-BOOK ON PRACTICAL SOLID OR DESCRIPTIVE GEOMETRY. By D. D. LOW. Longmans & Co.

The difference between this country and France in estimating the utility of descriptive geometry may be judged from the volumes which are found in the Christian Brothers' collection at South Kensington. They are intended to be used by boys who will be artisans, but they are more elaborate than those which are used by professional students in England. Mr. Low, who has published a treatise on the subject, claims consideration because it is small. There is some difficulty in obtaining for descriptive geometry that interest to which it is entitled, and it is only by tact on the part of the teacher that the rudiments can be mastered by the majority of pupils. Mr. Low has adopted the plan of introducing a great number of exercises after every problem where they are necessary, and in this way the student is prepared to deal with the examination papers, which are also given. The author appears to be qualified to treat the subject, and the book, if not exhaustive, is equal to the requirements of ordinary students.

NOTES ON PICTURES IN THE OLD PINAKOTHEK AT MUNICH. By CHARLES L. EASTLAKE, F.R.I.B.A. Longmans & Co.

It is needless to speak of the importance of the collection of paintings which is in the Pinakothek at Munich, having been brought there from several of the Bavarian galleries and elsewhere. So many styles are represented that there was reason to paint the ceilings with figures that were typical of the history of art. Mr. Eastlake has prepared a volume of Notes, which will enable visitors to discover the most interesting pictures, and will suggest the best qualities in them. The descriptions are pithy, and the criticisms are given without bias. If there are defects they are not concealed. A book inspired by such a straightforward style and so much knowledge must have an influence on travellers, and overcome the insincerity of the praises which are often heard in galleries. The type has been well chosen for its size and legibility. There are many illustrations of a diagrammatic character.

PERSPECTIVE EXPLAINED AND ILLUSTRATED. By GEORGE SYDENHAM CLARKE, Captain R.E. E. & F. N. Spon.

The title-page of this book bears 1884 as the date of publication, otherwise it might be supposed to have appeared many years ago. The majority of the examples are worked out in a way that was in vogue thirty years since, and the old-fashioned style is not improved by having some of the diagrams turned upside down. The principal defect is the cumbrousness of the solutions. Such a problem as is represented in figure 15 could be solved with far fewer lines. It is impossible to teach the whole art of perspective in fifty pages, and abstracts like Captain Clarke's do not shorten the student's difficulties.

### WORKS IN PROGRESS.

**Messrs. C. Isler & Co.**, of 88 Southwark Street, London, S.E., are now engaged fixing a 16-inch boring for the Hydraulic Engineering Company, at 110 Cannon Street, E.C. They are also engaged in deepening a well in the solid rock at the Anchor Brewery, Stonehouse, Devon.

**The American Elevator Company** obtained the contract for one first-class passenger lift to be erected in the new office buildings of Messrs. Mark Patrick & Sons, in Warnford Court, opposite the Stock Exchange, and of which Mr. Charles Reilly, is the architect. This is to be a "Standard" hydraulic lift, and will be a fair type of those which are now in general use in office buildings in New York and the United States. The car will also be of the most approved American pattern, and will serve to show its occupants the style which is usually adopted in that country.

### NEW BUILDINGS.

**Berkhamsted.**—The new banking premises for the London and County Banking Company, Limited, lately erected by Messrs. Taylor & Grist, builders, of Aylesbury, from the designs of Messrs. Batterbury & Huxley, architects, of Berkhamsted and London, were opened on Wednesday for business.

**Public Buildings, Kirkwall.**—The foundation-stones of the Municipal Buildings and the Masonic Hall have been laid. Both buildings have been designed by Mr. T. V. Peace, architect, Kirkwall. The site of the town hall is opposite St. Magnus's Cathedral, and the style adopted for the building is Scottish Baronial. The contractors are Messrs. Baikie & Son. The contract for the Masonic Hall has not yet been let. The ventilation will be by Boyle's air-pump ventilators.

**Assembly Rooms, Edgbaston.**—This building is nearly completed. The site at the corner of the Hagley and Francis Roads presented some difficulties, as it resembles a right-angled triangle. A broad staircase leads to a suite of rooms consisting of a ball-room, measuring 70 feet by 40 feet, drawing-room, galleries, refreshment-rooms, &c. On the ground floor is a supper-room of the same size as the ball-room. A restaurant forms part of the building. The construction and furnishing will cost about 11,200*l.* The works have been carried out by Mr. John Bowen, under the direction of the architects, Messrs. Osborn & Reading, Bennett's Hill, Birmingham.

### NOTES ON NOVELTIES.

**Artificial Granite Paving.**—With the number of materials for paving now in the market, it is not to be wondered at that local boards and vestries are at times in doubt as to which to adopt. They are sometimes induced to try one kind that is favourably brought to their notice; but should this happen to turn out inefficient, it is difficult to persuade them to venture upon another that they are unacquainted with. But, on the other hand, this feeling can be carried to excess; and if they exhibit an indifference to an article when they know nothing of its value, they may be doing an injustice to the ratepayers generally. We do not advocate an indiscriminate use of any or every new material that may be introduced simply because it is recommended by its inventors; but when a material is offered them of which undoubted testimony can be given of its good wearing properties, and that its first cost is less than any other possessing the same advantages, it seems little less than egotistical to ignore it. We are induced to make these remarks owing to a visit we paid a few days since to the neighbourhood of Ealing, to examine some artificial granite pavement that has been laid for about five years, and appears as good to-day as when first put down. We shall no doubt be told there is nothing new in granitic pavement, that it is only concrete in another form, &c. To the first we do not object, but we are not at all disposed to place ordinary concrete in the same category as the pavement of which we are about to speak. And we may reasonably ask how it is that with the advantage that we think can be clearly shown to attach to an artificial granite pavement, that it has not come into more extensive use for footpaths. The reason, perhaps, is twofold; first, the very few who have introduced this substance have confined their operations to stables and such places; and, secondly, that when brought out as a footpath for streets, it was laid down in a manner not suited for such requirements. Mr. William J. Taylor, of Church Street, Chelsea, is one of the few persons who have paid attention to this subject. For about eighteen years he has constantly been employed in laying down granitic footways in yards and stables, which have been set in brick-like form, and ample testimony is forthcoming of the indestructible character of the material as well as of its economic features. A few years since Mr. Taylor commenced to introduce it as a foot pavement, and with this "new departure" his difficulties, so to speak, began. While he could obtain private orders for his pavement in the direction we have named, when it became a question of public footpaths, vestries and local boards had to be appealed to, and in nearly every instance he has been told that if he chose to lay down a certain length at his own expense as a test he may do so.

Even in Chelsea, where he has been an inhabitant and ratepayer for many years, the same answer has been given to his applications, and although he can point to a portion of Ealing where it has been laid for some five years, it has not been of any avail to him. We may now ask what is artificial granitic pavement, and how should it be laid to make it most useful and economical as a footpath? As we introduce it to our readers it is composed of the small chippings of granite obtained from the quarries, mixed with Portland cement, and "manufactured" on the spot in which it is to be used. Granite, as we all know, is the hardest stone, and when mixed with a proper proportion of "Portland" must necessarily make as hard a footpath as anything we can use. But the manner in which it is laid is an important consideration. If set down as asphalt in one continuous range without a break, its disadvantages in a certain sense appear. Supposing it becomes necessary to take up a portion of the footpath to gain access to water or gas-pipes, as in the case of asphalt, a general break-up of the footpath must take place at an unnecessary cost, but if the pavement is laid in blocks of about the size of York stone, and if when laying down care is taken to note where it may be hereafter necessary to raise these blocks, the maximum of difficulties is guarded against. It is in this manner Mr. Taylor lays his pavement. Noting where these pipes occur, a small incision is made at each side of the block and filled up with a material easily removable; this enables the first block to be raised, and the others then follow without difficulty. As the blocks are laid down, a slip of wood about a half-inch wide is placed between each, which gives them the appearance of ordinary paving-stones, and the advantage of Mr. Taylor's plan must be palpable to all. The blocks are 2 inches in thickness, and in place of the smooth surface offered by stone, asphalt, &c., often dangerous, there is always a comparative rough surface in existence, pleasant to the senses while walking over, and decidedly safe under all conditions of weather. It now only remains to speak of the cost. Laid down as we have described, Mr. Taylor's pavement can be set for from 3*s.* 6*d.* to 4*s.* per yard super, and as compared with York stone, artificial stone, or asphalt, we need not say it bears most favourable comparison. Tar pavement may be a trifle less in first cost, but as regards wear in thoroughfares with much traffic, it cannot be taken into consideration. The value then of the artificial granite pavement appears to consist in its being laid in blocks of about the size of ordinary paving-stones, regard being made for taking up in case of necessity, in a proper admixture of Portland cement with the particles of granite, and good workmanship in setting, when, from an economical point of view, we believe it will prove the cheapest foot-paving that can be used.

### GENERAL.

**Sir A. B. Walker** has written to the Mayor of Liverpool offering to defray the entire cost of the additions to the Walker Art Gallery, lately carried out by the Corporation at an expense of 12,000*l.* The gallery originally cost 6,000*l.*

**A Nave Porch**, designed by Mr. Sidney Gambier Parry, has been erected at the parish church, Bishopstone.

**A Peal of Bells** is to be placed in Hagley Church as a memorial of the rector, the late Canon Lyttelton.

**The Somerset Archaeological Society** held its annual gathering at Shepton Mallet on Tuesday and Wednesday. Mr. E. A. Freeman delivered the inaugural address on architectural restoration.

**Messrs. Robert Boyle & Son**, ventilating engineers, of 64 Holborn Viaduct and Glasgow, have been awarded the highest and only prize (silver medal) given for ventilators at the International Exhibition, London, for their patent self-acting air pump ventilators and system of ventilation.

**The Earl of Moray** has sent a subscription of 1,000*l.* to the Edinburgh University Buildings Completion Fund. His lordship had already subscribed 1,525*l.*

**A Lattice Bridge**, 80 feet span, is in course of erection over the ornamental water opposite Clarence Gate in Regent's Park. It will open a direct communication between Hyde Park Corner and the Zoological Gardens.

**The Police Report for 1883** states that 21,110 houses were built during the year, forming 361 new streets, and one new square, covering a distance of 56 miles and 84 yards. The operations of the building trade were rather restricted, the number of new houses and the mileage of the new streets showing a considerable decrease as compared with the previous few years, although, as compared with 1873, the number of houses increased threefold, and the length of the new streets more than doubled.

**The Gold Medal** of the International Exhibition, Crystal Palace, 1884, has been awarded to Messrs. Le Grand & Sutcliff, artesian well engineers, of 100 Bunhill Row, London, for their well-known "Abyssinian" tube wells and artesian boring appliances. Some indication of the wide extent of the well-boring operations of this firm is shown from the fact that, within the last few years, the aggregate number of feet of artesian wells bored by them amounts to between three and four miles. This is exclusive of borings for hydraulic lifts and the smaller "Abyssinian" tube wells sunk, amounting to many thousands of feet.

# SUPPLEMENT

TO THE

# ARCHITECT

## CONTRACTS, COMPETITIONS, AND TENDERS.

LONDON, AUGUST 30, 1884.

### COMPETITIONS OPEN.

**BIDEFORD.**—Sept. 22.—The Trustees of the Bideford Bridge Trust invite Competitive Designs for the Erection of a Block of Buildings suitable for a Post Office on site of Premises in High Street. Premiums of 20*l*. and 10*l*. The cost of carrying out any of the Designs not to exceed 800*l*.

**BOMBAY.**—Nov. 6.—The Municipal Commissioner of Bombay invites Designs and Estimates for a New Municipal Hall and Offices, which must be sent to his Office by Twelve noon, on Nov. 6. A Premium of 5,000 rs. will be given for the Design most approved of by the Commissioner, with the assistance of a Committee of the Corporation; 3,000 rs. for the second, and 2,000 rs. for the third. The total cost of the buildings is not to exceed 5 lacs (5,00,000 rs.). Mr. E. C. K. Ollivant, Municipal Commissioner's Office, Bombay, or at Messrs. E. W. & R. Oliver, 1 Corbet Court, Gracechurch Street, London.

**REDRUTH (CORNWALL).**—Sept. 13.—*School.*—The Redruth School Board offer a Premium of 25*l*. for the best Plans (Elevation and Detailed Drawings), to be selected by themselves, for a School, to be erected at Trewirgie, Redruth, to accommodate 700 Children (350 Boys and 350 Girls and Infants). Total cost not to exceed 3,500*l*. Mr. Charles Bawden, Clerk, Heanton Place, Redruth.

**STOCKPORT.**—Oct. 1.—Designs are invited for Public Baths. Premiums of £50, £30, and £20. Mr. Walter Hyde, Town Clerk, Stockport.

### CONTRACTS OPEN.

**BATLEY.**—Aug. 30.—For a Warehouse in Tichborne Street, Staincliffe, Batley. Mr. J. T. Law, 64 Commercial Street, Batley, Architect.

**BRADFORD.**—Sept. 2.—For Additions and Alterations to Warehouse, Chapel Street. Mr. William Longley, Architect, Charles Street, Bradford.

**BRADFORD.**—Sept. 9.—For Construction of Station. Plans at the Engineer's Office, Hunt's Bank, Manchester.

**BRIDPORT HARBOUR.**—Sept. 2.—For Building Ten Houses. Messrs. Prior & Alexander, Architects, 17 Southampton Street, Bloomsbury Square, W.C.

**BYFLEET.**—For Building Three Cottages. Mr. Welch, Architect, Chertsey.

**CARDIFF.**—Sept. 1.—For Building Sheds at Ely Paper Works. Messrs. Evans & Owens, Ely Paper Works, Cardiff.

**CHIPPING SODBURY.**—Sept. 2.—For Alterations and Additions to Premises in High Street. Mr. J. D. B. Trenfield, Chipping Sodbury.

**CLAINES.**—Sept. 4.—For Construction of Pipe Sewers, Manholes, Receiving Tank, Engine House, Filter Beds, Roads, Fences, and Works in connection with the Sewerage Scheme of the District. Mr. A. H. Parker, Surveyor, 5 Foregate Street, Worcester.

**CORK.**—Sept. 2.—For Building Additional Wards and Dispensary Accommodation to the General Hospital, Queenstown. Mr. W. H. Hill, Architect, 15 Marlborough Street, Cork.

**CORNWALL.**—Sept. 2.—For Erection of Viaduct in Masonry at Guildford, Hayle, and at Redruth. The Engineer, Paddington Station.

**CROOK.**—Aug. 30.—For Building St. John's Church, Sunnybrow. Messrs. Oliver & Leeson, Architects, Bank Chambers, Mosley Street, Newcastle-on-Tyne.

**DARLINGTON.**—Sept. 9.—For Reseating St. Cuthbert's Church. Mr. Francis Parr, Architect, 6 Duke Street, Darlington.

**DUNDEE.**—Sept. 1.—For Building Engine Shed (286 feet long and 181 feet wide). Mr. Burr, Engineer, Northern Division, Caledonian Railway, Perth.

**GOOLE.**—Sept. 1.—For Building Co-operative Stores, Estcourt Street. Mr. Holton, Architect, Bond Street, Dewsbury.

**GUILDFORD.**—Sept. 3.—For Building Board School for 500 Children, Charlotteville. Mr. William G. Lower, Architect, 106 High Street, Guildford.

**HALIFAX.**—Sept. 8.—For Extension of Passenger Station. Plans at the Engineer's Office, Hunt's Bank, Manchester.

**HALIFAX.**—Sept. 6.—For Building Engine-house and Chimney at the Albert Reservoir. Mr. Escott, Borough Surveyor, Town Hall, Halifax.

**HALTWHISTLE.**—Sept. 3.—For Building Goods Station. Mr. William Bell, Architect, Central Station, Newcastle-on-Tyne.

**HAMMERSMITH.**—Oct. 2.—For Rebuilding Superstructure and Strengthening Hammersmith Bridge, Construction of Temporary Bridge, &c. Sir J. W. Bazalgette, Spring Gardens, S.W.

**KEIGHLEY.**—Aug. 30.—For Building Boundary Wall to Mission Church. Mr. J. B. Bailey, Architect, North Street, Keighley.

**KENDAL.**—Sept. 4.—For Building Mission Room at Storth, Sandside. Mr. Stephen Shaw, Architect, Kendal.

**KIDDERMINSTER.**—For Building Offices and Warehouses, Mill Street. Mr. J. M. Gething, Architect, 7 Church Street, Kidderminster.

**KILLARNEY.**—For Additions to Laundry at Lunatic Asylum. Mr. J. F. Fuller, Architect, 179 Great Brunswick Street, Dublin.

**KILNHURST.**—Aug. 30.—For Building Chancel and Vestry to Church. Mr. T. W. Roome, Architect, Sandhill Grange, Rawmarsh.

**KNOCKADOON.**—Sept. 17.—For Construction of Boat Slip and Platform, Rook Excavation, &c. Office of Public Works, Dublin.

**LETTERKENNY.**—Sept. 1.—For Additions to District Lunatic Asylum. Mr. Morley, Building Surveyor, Commercial Buildings, Dublin.

**LINCHMERE.**—Aug. 30.—For Building Board School and Teacher's Residence. Mr. Edward Eames, Surveyor, Linch, near Midhurst.

**LOCHMADDY.**—Aug. 30.—For Additions to Hotel. Messrs. Kinnear & Peddie, Architects, 3 St. Charlotte Street, Edinburgh.

**MATLOCK BRIDGE.**—Aug. 30.—For Pulling Down and Rebuilding Second Quarter New Central Block of Hydro-pathic Establishment. Mr. George E. Statham, Architect, Wheeler Gate, Nottingham, and Matlock Bridge.

**MINTLAW.**—Sept. 2.—For Building Dwelling-house at Station. The Engineer, Waterloo Station, Aberdeen.

**NELSON.**—Sept. 5.—For Additions and Alterations to Methodist Chapel. Mr. Thomas Bell, Architect, 14 Grimshawe Street, Burnley.

**NEWPORT.**—Aug. 30.—For Erection of Buildings for the Patent Fuel Company. Mr. B. S. Jacob, 71 St. Mary Street, Cardiff, and Hull.

**NOTTINGHAM.**—For Building Board School for 960 Children, Carlton Road. Mr. A. N. Bromley, Architect, Weekday Cross, Nottingham.

**PATCHAM.**—Sept. 1.—For Building Engine House, Coal Store, &c. Messrs. Easton & Co., 11 Delahay Street, Westminster.

**RIPPONDEN.**—Sept. 1.—For Building Villa. Mr. S. Wilkinson, Architect, Sowerby Bridge.

**ROCHDALE.**—Sept. 1.—For Additions to Chapel. Mr. Benjamin Heape, 7 Baillie Street, Rochdale.

**SEAHAM HARBOUR.**—Aug. 30.—For Building Co-operative Store, Manager's House, and other Buildings. Mr. George R. Forster, Architect, Seaham Harbour.

**SHEPTON MALLET.**—Aug. 30.—For Building Sexey's County School at Doptling. Mr. G. J. Skipper, Architect, Opie Street, Norwich.

**SHIPTON-UNDER-WYCHWOOD.**—Sept. 6.—For Building Beaconsfield Hall. Mr. T. Brookes, Shipton, Chipping Norton.

AWARDED SEVEN PRIZES FOR SUPERIORITY, INCLUDING PARIS GRAND MEDAL, 1878, THE CERTIFICATE OF MERIT OF THE SANITARY INSTITUTION OF GREAT BRITAIN, AND THE AWARD OF MERIT AT THE INTERNATIONAL EXHIBITION, 1881.

TO ARCHITECTS.—THE BRICK of the FUTURE, that shall not get dingy or sooty like other Bricks, but, being of a Semi-Vitreous nature, will maintain a clean and washable surface.

## FACING BRICKS AND BRICK ORNAMENT OF TRUE TERRA-COTTA, AS ALSO ARCHITECTURAL WORK, IN WHITE AND WARM-TINTED BUFF.

Made from the Finest Terra-cotta and Stoneware Clays, of a warm and pleasing appearance, of beautiful and superior quality and finish, non-absorbent, acid, fire, and alkali proof, will resist the most severe frosts, and when tested were found to withstand a pressure of 445 tons to the square foot. They have been used in the most exposed parts on the North and South Coasts, and being true Terra-cotta, are warranted imperishable.

Pattern Sheets and Price Lists of superior Glazed Stoneware Sanitary Pipes, and Fire Clay Goods, Chimney Tops, &c., on application.

Sole Manufacturers:—CANDY & CO., Limited, GREAT WESTERN POTTERIES, NEWTON ABBOT, AND 11 QUEEN VICTORIA STREET, LONDON, E.C. Who are also Sole Makers of the celebrated "Granite Vitrified" Paving Bricks for Yards, Stables, and Footpaths, and "Granite Vitrified" Damp-proof Building Bricks, as used by H.M. Government for dock construction, &c. Samples free to Architects and Engineers.

**SOUTH SHIELDS.**—Sept. 1.—For Erection of Dwarf Wall with Iron Palisading and Gardener's House, at the Lawe. The Borough Engineer, Chapter Row, South Shields.

**STANWIX.**—Sept. 5.—For Building Board Schools and Master's House. Mr. C. J. Ferguson, 50 English Street, Carlisle.

**STRINGS.**—For Building Two Brick Cottages. Mr. Charles Hague, Crown Inn, Hawkgreen, Marple.

**SUNDERLAND.**—Sept. 1.—For Building Methodist Schools, Chester Road. Mr. Joseph Shields, Architect, Blackett's Buildings, Sunderland.

**TODMORDEN.**—Sept. 26.—For Construction of Reservoir, Ramsden Clough. Mr. James Farrar, C.E., Market Street, Bury.

**TUNSTALL, NEAR ACLE.**—Sept. 3.—For Building Stable, Wagon Lodge, Piggeries, &c., Church Farm. Mr. Arthur J. Lacey, Architect, Orford Hill, Norwich.

## TENDERS.

### ABERDEEN.

For Building Boiler and Engine Houses, &c., at Cults. Mr. W. BOULTON, Surveyor, Aberdeen.

#### Accepted Tenders.

Duguid, builder	£1,513	1	6
Dinnes & Middleton, joiner	322	1	0
Pirie, slater	48	13	11
Smith, plumber	44	9	9
Garvie & Son, painter	30	17	6
Stephen, plasterer	11	0	0

All of Aberdeen.

### ABERSYCHAN.

For Construction of Road (44 chains) with Walling, Fences, &c., Abersychan. Mr. E. COOKE, Surveyor.

Pickthall & Sons, Merthyr Tydfil	£1,341	7	8
Thomas, Pontypool	1,175	10	6
Cullimore, Abersychan	1,112	0	0
Thomas & Jenkins, Trevelin	1,088	0	0
Adamson, Tredegar	965	0	0
Chapman, Pontnewynydd	950	0	0
Williams, Fochriw	897	18	4
Pearson, Merthyr	833	2	0
CABLE, Abersychan (accepted)	824	17	6
Surveyor's Estimate	863	13	4

### BIRKENHEAD.

For Works, Beckwith Street to St. Anne Street, Birkenhead.

Peen, Seacombe	£463	10	6
Chadwick, Liverpool	431	11	0
Gass, Birkenhead	415	13	0
Jones, Birkenhead	398	18	3
Maddocks & Co., Birkenhead	381	0	0
Povall, Birkenhead	361	14	4
Riddell, Birkenhead	358	9	1

### BRENTFORD.

For Alterations and Additions to No. 173 High Street, Brentford, for Mr. Geo. Stone. Mr. CHAS. J. GLADMAN, A.R.I.B.A., Architect.

Gibson	£384	10	0
Nye	265	0	0
Dorey	258	18	10
Barnes	244	3	10

### CANTERBURY.

For Works of Partial Reconstruction of the Sidney Cooper School Art Gallery. Mr. J. G. HALL, Architect.

Gentry & Son	£693	10	0
--------------	------	----	---

### CARDIFF.

For Erection of Shedding, Horse Boxes, Grand Stand, &c., for the Horse Show, Cardiff.

Lock, Cardiff	£346	10	0
---------------	------	----	---

### CARDIGAN.

For Building Business Premises, Cardigan, for Mr. J. James. Mr. GEORGE MORGAN, Architect, Carmarthen.

THOMAS & LEWIS, New Castle, Emlyn (accepted)	£1,910	0	0
--	--------	---	---

### COLD KIRBY.

For Erection of Farmhouse and Buildings, Cold Kirby, Hambleton. Mr. BLESSLEY, Architect, Middlesbrough.

#### Accepted Tenders.

Sourr, mason.

Thirkill, joiner.

Mascall, slater.

### CORK.

For Building Twenty Houses, for the Cork Villa and House Company. Mr. ROBERT WALKER, Architect, 17 South Mall, Cork. Quantities supplied.

MARTIN (accepted)	£9,091	8	0
Roberts	8,800	0	0
T. O'Flynn	8,746	5	5
Fitzgerald	8,256	0	0
E. & P. O'Flynn	8,235	0	0
Hill	7,825	0	0
Delany	7,786	0	0

### DERBY.

For Building Houses, Dexter Street, Derby. Mr. R. W. H. MASON, Architect, Derby.

Musgrave	£2,602	0	0
Pemberton	2,458	10	0
Hewitt	2,400	0	0
Hilton	2,395	0	0
Brown	2,364	0	0
Spencer	2,304	4	0
Brown & Son	2,290	0	0
Yeamaus	2,279	0	0
SMITH & WESTON (accepted)	2,218	0	0
Slater (withdrawn)	2,200	0	0

### DARLINGTON.

For Construction of Forcing House, Public Park, Darlington.

Alton	£138	15	0
Stairmand	137	4	9
Richardson & Co.	127	0	0
Denham	110	0	0

### DENTON.

For Branch Stores and Dwelling-houses for the Denton and Haughton Co-operative Society, Limited, Denton, near Manchester. Mr. T. COOK, Architect, Surveyor, &c., 8 Victoria Buildings, Victoria Street, Manchester. Quantities by the Architect.

Storer, Denton	2,290	0	0

\* Too late.

### GRAYS.

For Erection of a Shop and Bakehouse at William Street, Grays, for Mr. J. R. Banks. Mr. E. CLERK ALLAM, M.S.A., Architect.

BROWN (accepted)	£868	0	0
------------------	------	---	---

### GRAYS THURROCK.

For Erection of Additional Schoolrooms and Infant Mistress's Residence at Quarry Hill Board School, for the Grays Thurrock School Board. Mr. E. CLERK ALLAM, M.S.A., Architect.

Stafford, London	£6,298	0	0
Seager, Gravesend	4,570	0	0
Thompson & Tweed, London	3,279	0	0
Wood, Chelmsford	3,182	0	0
Mower, London	3,035	0	0
Webb, London	2,925	0	0
Hawkins, London	2,741	0	0
Aldridge & Jenvey, London	2,683	0	0
CARTER, Grays (accepted)	2,635	0	0

### KETTERING.

For Erection of Sewerage Works, Kettering. Mr. R. W. JOHNSON, Surveyor, Kettering.

Cooke & Co., Battersea	£5,590	0	0
Corrie & Co., Litchfield	5,327	0	0
E. Barlow, Rothwell	5,273	0	0
Sanders, Southampton	4,748	0	0
Dickson, St Albans	4,800	0	0
C. & F. Henson, Kettering	4,850	0	0
F. Barlow, Kettering	4,168	10	0
G. V. HENSON, Kettering (accepted)	4,100	0	0

### LEICESTER.

For Erection of Vicarage House for St. Nicholas's Church, Leicester. Mr. THOMAS P. BOWN, Architect, New Street, Leicester.

TEBBATT (accepted).

### LIVERPOOL.

For Heating Apparatus, Newhall Hill Church, Birmingham.

RENTON GIBBS, Liverpool (accepted).

For Heating Ladies' School, The Mount, Malvern.

RENTON GIBBS, Liverpool (accepted).

### LLANDOVERY.

For the Renovation of the Baptist Chapel, Llandovery, South Wales. Mr. GEORGE MORGAN, Architect, Carmarthen.

HUGHES (accepted)	£245	0	0
-------------------	------	---	---

### LONDON.

For Works to Roads, &c., at Workhouse and Infirmary, Kensington.

Mears	£1,532	0	0
Nowell & Robson	1,497	0	0
MOWLEM & Co. (accepted)	1,320	0	0
Architect's Estimate	1,300	0	0

For Erection of Studio, Golder's Hill, Hampstead, for Sir J. Spencer Wells, Bart. Mr. ARTHUR VERNON, Architect, 26 Great George Street, Westminster and High Wycombe.

BIRD (accepted)	£316	0	0
-----------------	------	---	---

For Completing Five Houses, Gascony Avenue, Kilburn, for Mr. Geo. Gladman. Mr. CHAS. J. GLADMAN, A.R.I.B.A., Architect.

Falkner	£1,275	0	0
Barnes (too late)	1,232	2	9
Pryor	1,175	0	0
Barnett	1,050	0	0

For Alterations and Repairs to No. 34 Baker Street, for Mr. Arthur Canton, L.D.S. Mr. CHAS. J. GLADMAN, A.R.I.B.A., Architect.

D. D. & A. Brown	£217	0	0
J. Brown	875	13	0

**GRUNDY'S PATENT  
WARM-AIR  
VENTILATING FIRE GRATE.**

The novelty, superiority, and advantage of this patent consist in the heating surface being greater than any other Fire-grate introduced to the public. It is very simple in construction, and is made in the form of a Stove, the back of which is semicircular in shape, with gills behind and smoke-nozzle on top, all cast in one piece. The same can be attached to any design of a Register or Stove front. It is very suitable for schools, class-rooms, waiting-rooms, hospitals, offices, dormitories, and dwelling-houses, from the cottage to the mansion. Design and specification post free on application.

TESTIMONIALS.  
"9 Victoria Chambers, Westminster, S.W."  
"June 10, 1884."  
"SIR,—I have much pleasure in testifying to the efficiency of your patent Warm-Air Fire Grate. It has been very successful, and given every satisfaction where I have used it."  
"Yours, &c."  
"JAMES WEIR, F.R.I.B.A."

"Baptist Chapel, Clapham Common, London. Richard Webb, Pastor, 10 Grafton Square."  
"February 15, 1884."

"DEAR MR. GRUNDY,—I have pleasure in testifying to the excellency and efficiency of your patent Fire-Grate. It is the most charming invention for heating a large room I have ever known. I shall have pleasure in showing it to anyone who wish to have their schools or rooms pleasantly and efficiently heated."

From James Garry, Esq., Architect, West Hartlepool, July 1884.

"DEAR SIR,—I have very great pleasure in stating that the first stove, or patent warm-air ventilating fire grate, adopted by me in school at Seaton, and a second in a Cocoa Palace, have given such satisfaction that I now order eleven to be inserted in New Upper Grade Schools in course of erection at West Hartlepool. They are the most economical, efficient, and easily managed stove at present before the public."  
"Mr. John Grundy."

Apply to JOHN GRUNDY, 30 Duncan Terrace, City Road, London.  
Works—TYLDESLEY, near MANCHESTER.

DESIGN FOR ADMIRALTY & WAR OFFICES

# The Architect.

## THE HARMONY OF ARCHITECTURE WITH OTHER ARTS.

CLEVER correspondent in our last issue sets forth in very few words a strong point in architectural criticism. Architecture, he suggests, can always know its own artistic condition by simply considering how far it is in concord with other contemporaneous arts; and this rule he applies to English architecture of the present and recent times by shrewdly reminding us that it has always been "the sport of fashion in practical antiquarianism," as contrasted with the state of art in France, "where antiquarianism

is practically unknown."

The contrast between the two nations which occupy the opposite shores of the Channel—one of the most striking instances in the world's history of the abiding intellectual heredity of race—is scarcely in any other matter so well illustrated as in the difference of principle which appears in their architectural design. The remarkable era of the nineteenth century opened, as everybody knows, in the midst of European revolution, a revolt against what remained of Mediæval feudalism, initiated in France but prefigured in British America. It may seem paradoxical to say that one outcome of this was modern Greek architecture on one side of the Channel and modern Gothic on the other; but a little reflection makes it clear enough that this was really so. The passionate emotions evoked by the sudden overthrow of privileged authority seems to have fixed the attention of the French directly and permanently upon the classical antique, which it identified with all the glories of freedom. The distrust, on the other hand, of uncompromising and reckless reform, and a feeling of resentment against the actual violence of its career, led the entirely different intelligence of the English to seek an anchorage in patriotic sentimentality; and when this gave rise, as we can easily understand it would, to a certain reaction in favour of feudal associations, if only of a superficial sort, the way was obviously opened to an eventual rehabilitation of Mediævalism. In the Napoleonic war, looked at from an artistic point of view, France was fighting for an escape from the Mediævalism out of which she had only just emerged by an imitation of the old-world Classicism which it was so easy to regard as the only alternative; whilst England, having escaped from the practical inconveniences of Mediævalism long before, was enabled to set up for an idol her own "good old times," and to do battle for the memory of them with vast satisfaction, and with ultimate success. It does not require in these days a reference to the mere doctrine of the association of ideas to satisfy the student of art history that here there were two diametrically adverse intellectual principles at work, on the opposite shores of a narrow sea, out of whose action sooner or later two diametrically adverse developments of artistic design must, amongst other things, arise.

Thus it is that while PUGIN was so great a success in England, VIOLETT LE DUC (we say it with all respect) has been a failure in France; PUGIN, a mere extatic, too, appealing to "a nation of shopkeepers," and VIOLETT LE DUC, a deliberate philosopher, addressing himself to the most accomplished people in the world. For in France (in the words of our correspondent) "antiquarianism is practically unknown" still; whilst in England it seems impossible to say that we shall ever repudiate its authority. We may even add that in France antiquarian architecture, whenever attempted, has proved to be at the best but a spiritless adventure, whereas in England it has developed, in spite of all inherent faults, into what we may call an authentic counterfeit, the most admirable in its way that has ever been accomplished, perhaps the only really admirable thing of the kind in artistic history.

This being so, we cannot, however, shut our eyes to the obvious truth of the maxim that, when architecture is seen to be in a condition of discordance with the other arts of the same time and place, this cannot be right. In other words,

when the development of the arts in general exhibits a certain inferiority of character, which becomes the natural style of the country and the age, architecture ought surely to follow the same style; any deviation is unnatural; and, wherever an exceptional case is met with, a sufficient reason ought to be assignable for the exception, the *onus probandi* resting upon its defenders.

If we try to apply this maxim to the condition of English architecture at the present day, what do we find? Let us take church architecture. We visit some sufficiently important and good example of a new church; and it is of course at once apparent that the architect has designed it with the most painstaking perseverance of detail in accordance with the corresponding edifices of the thirteenth or fourteenth century. Not only is the imitation of the originals so extremely faithful, and so successful, that we are constrained to acknowledge a vitality in it which is almost equivalent to authenticity, but we perceive that the sculptures of the reredos, the carvings of the enrichments, the glass pictures in the windows, and the figures and foliage in the decorations and symbols, are all executed in a certain peculiar manner which is in full harmony with the architecture, and indeed is found to be equally imitative of the style actually exhibited in the ancient examples. Everything is still so thoroughly characteristic that even the most cynical philosopher, if he be able to understand what he sees, must surely recognise the effect as high art. So far, then, so well; and we go to the exhibition of the Royal Academy to look at the pictures and statuary. Now it is idle for anyone to intercept our progress and take us to the Grosvenor Gallery; a question that need not be entered upon. Whether we accept the judgment of the great majority of successful artists, or that of the public at large, or that of the persons who buy the pictures and statuary, all with one accord will tell us, in spite of Grosvenor Galleries, that the works at the Royal Academy are as matter of fact the true representative works of the country and the age. Do we find, then, that these are in accord with what we have been inspecting—and admiring—at the new church? Most emphatically not. The painting and sculpture of the current age, that is to say, are not by any means the painting and sculpture of the thirteenth or fourteenth century, but of the nineteenth. Therefore, if the architecture of the new church is in accord with the ancient work of the other arts, and this ancient work is out of accord with the other arts of the current age, then it is quite clear that the architecture of the new church is out of accord with the other arts of the day, and consequently an anachronism. How far, then, may this be recognised as a legitimate exception to the rule?

There are many reasons why the architecture of the Church of England should just now take a line of its own, without regarding the example (so to put the case) of the main body of painters and sculptors in the Royal Academy. There are hosts of excellent people throughout the country, as we all know, who cultivate more or less modern ideas of ecclesiastical matters; but the patriotic principle, in the form of an affection for old times, is perhaps in no other way so favourably entertained in England as in connection with the Church. Taking them all round, the English clergy are well deserving of the utmost esteem and love of the people; and no doubt the public confidence in them, within the limits of their own sphere, has long been, and still is, increasing. We need not inquire why it is that the clergy feel it to be desirable in such circumstances to cherish the special kind of patriotic feeling which identifies the fabric of a new church with the sanctity of an old one. But even if this were due to no more profound sentiment than a natural affection for the most interesting of all remains of an architectural kind that such a country as England can possess, this would be quite enough to justify a reliance upon Mediæval design as a means of awakening popular sympathy. In other words, the English people love their old churches; they are pleased to see them "restored" in the old style; and they are pleased to see them reproduced in new churches. Accordingly, throughout the religious movement of the last fifty years, the influence of architecture, as a strictly sentimental art, has been very great, and indeed so much so that, if a change of style were now to be accepted to any considerable extent, it is not too much to say that the interest of the lay public in church building would probably no longer be the same. This, therefore, may be assigned as the reason for regarding our ecclesiastical architecture as an exception to the general rule of the Harmony of the Arts. It need

scarcely be said further that, in such an enterprise as church building, the justification of an exceptional mannerism for architecture proper must obviously be an equal apology for carrying the same mannerism into all the auxiliary works of decoration, ornament, and furniture. The arts of the Church, therefore, if this argument be correct, may fairly be regarded as constituting an entirely separate scheme from the arts of the Municipality or the State.

The adoption of these revived Mediaevalist arts by the English Nonconformists and the Scotch Presbyterians may seem to be, in this view of the case, an unintelligible phenomenon; but it is not so. The reason obviously is that the universal acceptance of the Gothic style in the Establishment, and the artistic success with which its development has been conducted, have caused it to be regarded as the religious style, not of the Church, but of the nation; and (if the jest may be pardoned), just as the popular divine remarked that he could not see why the devil should have all the good music, so even the most hostile promoters of the building of opposition chapels and meeting-houses may be excused for not being able to see why the Establishment should have all the good architecture.

We leave the matter now in the good hands of our readers. The proposition we have so far endeavoured to elucidate is no doubt one of sound philosophy; and perhaps the very remarkable exception which we have so freely commented upon may serve indeed to prove the rule.

### ASSOCIATED DWELLINGS IN FRANCE.\*

THE French are so co-operative by nature or by habit it is a wonder that the principle of association has not been more often applied by them to the erection of buildings, and especially buildings for the working classes. The *ouvrier* of Paris is, as a rule, much worse housed than his London brother, and unless he lives outside the fortifications he has to pay a larger portion of his earnings for what is little more than a place for sleeping. He has, it is true, the advantage which is common to all the inhabitants of enjoying life out of doors, in the hours which remain after his day's work; but should he be compelled to stay in what ought to be his home, he is, according to English notions, surrounded by discomforts. The French builder has a genius for economising space, and whether the workman has one or more rooms they are sure to be small and stuffy. The sanitary accommodation must, from the size of the appartement, be badly placed. "Nous ne comprenons pas," says a French economist, "que bon nombre d'architectes placent les lieux d'aisance aux environs des cuisines." It should be remembered, too, that in most cases the *cuisine* serves also as a dining-room and general living room by day, while at night it is often used as a bedroom for the workman's children, if there are any. Fuel of all kinds and candles are costly in Paris, and a workman is rarely able to expend more than thirty shillings a year for heating and lighting. On a winter's day his room is dark and cold, and is far from being a pleasant abode. It is fortunate for him that in case of illness he is able to enter one of the numerous hospitals. Foreigners consider the Paris workman to be a light-hearted animal who is happy in a blue blouse, and needs nothing beyond what is to be found in a café, or a dancing-saloon, or a picture gallery. But it is impossible for any man who is not a philosopher to be contented with the dwellings which are occupied by the lower orders in Paris, and the gaiety is often no more than an effort to control bitter thoughts. The quietest find little difficulty in joining in the "Chant des Ouvriers," which does not suggest that France is elysium:—

Quel fruit tirons-nous des labeurs  
Qui courbent nos maigres échine ?  
Où vont les flots de nos sueurs ?  
Nous ne sommes que des machines.  
Nos Babels montent jusqu'au ciel ;  
La terre nous doit ses merveilles :  
Dès qu'elles ont fini leur miel  
Le maître chasse les abeilles.

\* "L'Economiste Pratique; Construction et Organisation des Crèches, Salles d'Asile, Ecoles, Habitations ouvrières, et Maisons d'Employés, Hôtels pour célibataires, Cuisines Economiques, Bains, Lavoirs, Cercles populaires, Nourriceries, Maternités, Dispensaires, Hôpitaux, Hospices, Asiles de Nuit, Postes de Secours, Mécanisme de prévoyance et de bienfaisance." Par Emile Cacheux, Ingénieur des Arts et Manufactures. Paris: Baudry et Cie.

When workmen are discontented in Paris it is ominous to the State; and therefore some attempts have been made to remove the grievances which come from defective dwellings. The first experiment appears to have been made in 1848 by M. VALADON. Then the late Emperor, who was an admirer of English institutions, in 1852 obtained an advance of ten millions of francs for model dwellings, but out of that sum not more than a fifth was appropriated for the advantage of working-men. It was said that accommodation was extremely limited. The rooms were so small that the table and the bed had to be turned up, or an occupant could not use the room. Parisians are accustomed to ascend many flights of stairs, but it was objected that the stairs were more numerous in the new buildings, and the tenants regarded themselves as martyrs. The Emperor then constructed some blocks of dwellings on a better system, and they were offered to a society of workmen who were able to subscribe a certain portion of the cost. Afterwards buildings were erected by the society, the money having been borrowed; but it is found that not more than three per cent. interest on the outlay can be gained. It is no wonder that the French capitalists are not eager to embark in similar undertakings.

M. EMILE CACHEUX, a civil engineer living in Paris, has been more fortunate. He has made many experiments, which he relates in a massive volume, that merits the attention of municipalities and philanthropists as well as of speculators. His first operations were at Lilas, near Paris, where he utilised 9,000 square mètres of land. The cheapest houses cost 4,400 frs., or with the site, well, walls, &c., the cost was 6,000 frs.; and M. CACHEUX believes that it is not possible to erect near Paris separate dwellings at a less rate. At Lilas there were four in a block, set back to back in pairs, each having a kitchen and dining-room on ground floor and two bedrooms above. The largest room measured 4 mètres by 3 mètres. In the Impasse Boileau at Passy-Auteuil a row of ten one-storey cottages was erected at a cost of 36,000 frs., and it was transferred without profit to a society by M. CACHEUX. One of the cottages can be obtained by twenty yearly payments of 438 frs. This is after the system of English building societies, which M. CACHEUX is eager to see extended in Paris. He has speculated largely in adopting it, and is satisfied when he obtains five per cent. on his outlay. At the present time a man who follows the example of M. CACHEUX is a benefactor to France. There are many eleemosynary institutions in the country which do not always exercise a beneficial influence, and on the other hand there are speculators who insist on enormous gains. It is apparently difficult to steer midway between almsgiving and avarice, and yet it is only by following such a course that the friends of the *ouvrier* will really aid him.

The need of dwellings is every day becoming more pressing, while the obstacles are increasing. There is, in the first place, the difficulty of finding sites. It is not long since the authorities were considering a project for utilising the ground covered by the fortifications as sites for workmen's houses. It was set aside. M. CACHEUX, who speaks from experience, asserts that "la ville de Paris ne voulut pas favoriser la création d'habitations ouvrières." M. SEILLER offered to erect twelve large wooden houses, if ground was ceded to him gratuitously, but he was obliged to pay a rent of a franc a mètre. The houses cost 105,000 frs. (the State giving 28,000 frs.), and forty-eight families were lodged in them. They consisted of a ground floor and a flat, the approach to the latter being by an external staircase. According to M. CACHEUX the tenants were satisfied with the comfort of the dwellings. But the site was required for some other purpose, and as re-erection would involve a loss of 40,000 frs., M. SEILLER demanded that his engagement should be cancelled. There is something to be said in favour of movable dwellings, and the subject has engaged the attention of several French architects.

M. MAURICE LE CHATRE and M. HENRY BARTHÉLEMY, an architect, have projected the erection of blocks of dwellings near the Parc Monceaux, which would contain 9,000 dwellings. Lighting, heating, as well as furnishing, would be undertaken by the company. There would be workshops, a bazaar for the sale of goods, schools, kitchens, bakeries, a crèche, a pharmacy, &c. Motive power would be supplied from a central engine. It is proposed to make the intending occupiers take up the shares of 2,500 frs., paying from 1 to 5 frs. a week. This will form a very remarkable settlement if it can

be carried out in its entirety. The establishment of a somewhat similar "cité" has been partly realised in the Faubourg St.-Antoine, the buildings having workshops on the ground-floors and dwellings on the upper floors. It is difficult in those cases to say with precision how far the rents would pay, but M. CACHEUX points out that if the City of Paris erected a hundred thousand chambers, there would be a return for the outlay in the increased amount paid for octroi duties, municipal taxes, and other imposts. Elsewhere much has been contributed by the municipal authorities. In Milan, 8,000 mètres of land have been given for sites for houses; in Lille a dividend of five per cent. has been guaranteed on the outlay required for erecting two hundred and fifty houses; Havre has contributed 25,000 frs. for the lighting and water supply of a workman's "cité." With so many precedents, it is likely that Paris will sooner or later endeavour to grapple with a difficulty that is almost as pressing as sewage disposal in London. The French doctors are generally opposed to the crowding of a large number of families under one roof, and they say that in times of epidemic there is an inevitable danger which outweighs the advantages. They join, however, in praise of the Mulhouse system, where there are separate houses and gardens, with public wash-houses and restaurants.

A French woman is expected to be a wage-earner, and whatever improvements may be introduced in the dwellings, the necessity will still exist for crèches, salles d'asile or écoles maternelles, and similar asylums. The second part of the book by M. CACHEUX is devoted to the subject, and several plates are given showing the arrangement of those institutions. In England crèches are only makeshifts, and the premises have not been designed for the use of infants, as they are in France. Judging from M. CACHEUX's book, the organisation is almost perfect, and everything is done to insure the health and happiness of the children. The difference between the two countries is suggested by the contrast between the simple forms which have to be filled up in England and the elaborate documents in use in France.

From the time of infancy a Frenchman is accustomed to live with his fellows in common, and, as he may not have means for cooking in his dwelling, it is not surprising that restaurants should be on a larger scale in France than in England. The French establishment for economical alimentation is almost unknown in this country. In several workshops a cooking apparatus has been set up, by which meals can be supplied very cheaply. In one, where dinners were given to children at 2½d., so exact were the measurements that there was only a deficit of 94 frs., although nearly 600,000 dinners were supplied. Some railway companies have erected refectories for their employes, and throughout the country there seems to be a competition with the restaurant-keepers. A dining-hall in Orleans is 40 mètres, or over 130 feet in length. The cooking apparatus for such places has to be on a corresponding scale, and the cauldrons have to be moved by machinery.

French apartments, for which a high rent is paid, are without any provision for a bath, and, as in other cases, recourse must be had to public establishments. Vapour baths, like those which are to be found all over Paris, do not exist in London. Yet they are admirable sanitary agents. The ventilation is so well managed that the bather is not oppressed by the heat. There is a greater variety of douches and showers than is to be found in an ordinary English bath, and the charge for admission is moderate. A vapour bath is, however, in the opinion of physicians, less efficacious and less safe than a Turkish bath, but it is cheaper to maintain, and this may explain its popularity in France.

There are other structures described by M. CACHEUX, such as clubhouses for workmen, dispensaries, economical hospitals, night asylums, and the like. His book suggests some of the differences between French and English architectural practice. Abroad it is necessary very often to provide for the accommodation of a large number of people. When men are in the habit of living so much together, it is natural that they should go a step further and become Socialists in one form or another. In our eyes there is little difference between some of the modern institutions of France and the phalansteres, which COULOMB GENGEMBRE designed for the Fourierists. In both economy of labour and expenditure was sought, and the planning was devised to attain that end. According to Mr. MILL, Fourierism recognised separate *menages* for all who preferred them, and no other community of living than that all the members should reside in the same pile of buildings, and

transact their buying and selling through as few agents as possible. The proposed "cités" and such towns as Mulhouse are practical illustrations of the principle, although all connection with Fourierism would be disowned. The buildings which are erected in modern France indicate the spirit of the age, and to-day, as during all past time, architecture becomes a revelation of thoughts which are otherwise unexpressed.

## ART EXHIBITION IN BRIGHTON.

A LOAN exhibition is about to be held in Brighton, with a view of obtaining funds to reduce the debt on the local art school which was opened in 1877. The exhibition will be on a large scale, and sufficient promises have been received from the owners of art treasures to justify the expectation that the exhibition will be the most comprehensive and interesting ever held in the county. The town council have given the use of the Corporation Picture Gallery, which will be lighted by incandescent electric lamps, and the Corn Exchange, whilst the authorities at South Kensington will also assist the scheme. Amongst those who have consented to assist the committee in selecting the works offered for exhibition will be:—Sir Philip Cunliffe Owen, Mr. J. C. Horsley, R.A.; Mr. Alma Tadema, R.A.; Mr. H. S. Marks, R.A.; Mr. Frank Holl, R.A.; Mr. P. R. Morris, A.R.A.; Mr. H. G. Hine, Mr. J. S. Forbes, and Mr. W. C. Quilter. Besides the paintings it is proposed to include in the collection in a separate department a feature to some extent suggested by the reproduction of Old London in the Health Exhibition, in the shape of a series of apartments furnished and fitted up to represent different periods of English domestic art, manners, and customs, the periods selected being the time of Elizabeth, the Puritan period, the Queen Anne period, and the time of the Georges.

## THE ARCHÆOLOGY OF PEMBROKESHIRE.\*

BY THE LORD BISHOP OF ST. DAVID'S.

I THINK the British Archæological Association has done wisely in choosing this small area as the field of its operations this year, and all the more wisely that it is so small. It has been, as I venture to think, a weak point in the arrangements of our greater archæological societies that at their annual meetings the members have been invited to travel over so much ground, and to go far afield, neglecting in some cases that which lay at their doors. I think the local societies have in some cases had an advantage over the two general societies in doing their local work more minutely and thoroughly, and in giving their members an opportunity of examining every inch of the ground. At the present meeting the Association will be compelled to act on the principle hitherto observed by the local societies by the exigencies of its present geographical position. For, except in one direction, it cannot go very far from Tenby without getting into the sea, or being entangled in the long tentacles of Milford Haven. So whatever we have to do we hope to be able to do it well. And now let us see what we have to do. I suppose we may, with sufficient accuracy for our present purpose, make a rough fivefold division of material antiquities according to date. I think it will not be inconvenient to classify them as primeval, Roman, post-Roman, mediæval, and post-Reformation, the last being, no doubt, a very awkward term, but I do not know how to express the notion better. The name, however, is unimportant, and the more so that I do not intend to refer to any memorials of that period. I have already said that the division is a rough one; the distinction of periods is not clearly defined, and they sometimes overlap one another. For it is plain that certain antiquities, which we call primeval, may date from or even after the Roman occupation of Britain. Some of the early Christian monuments, which we call post-Roman, may have had their origin during that occupation, although I do not suppose that any of them did. It is very hard to say where we are to place the beginning of the middle age, although it is perhaps not so hard to distinguish between the decay of Roman and the development of Mediæval art, while the latter did, as a matter of fact, linger on in some places even into the seventeenth century. Still, I think we must be content with the classification which I have made for lack of a better.

### *Prehistoric Remains.*

In primeval remains, Pembrokeshire is unusually rich; but, although the district in which Tenby stands is not without them, they are most abundant in the northern and north-western parts of the county. They may be divided into villages, fortresses, sepulchral remains, and early roads or track-ways. A good specimen of the first class was discovered not many years since on Stackpole Warren, and to this the attention of the Association will

\* An address delivered at the opening of the forty-first annual congress of the British Archæological Association at Tenby on Tuesday last.

be directed at its present meeting. Fortresses occupy many of the peninsular headlands of the Pembrokeshire coast, and many eminences in the interior. Some of them are of great size and complexity, and show considerable military skill. In some cases we have the fortress and village combined. Perhaps the best example of this combination in South Wales is visible in the well-defined village-fort on St. David's Head, where the foundations of the circular houses, forming a considerable group, are defended by a system of concentric walls, of which the masonry forming the face is in some places well preserved. By what race, or by what succession of races, these hill and cliff forts and villages were built, whether they belong to one age or many, whether they are not some of them post-Roman, whether they were used as places of permanent abode, or merely as places of occasional retreat, are questions which I would rather ask than attempt to answer, and the answers to which are perhaps still to seek. These objects are so numerous, and are so widely scattered throughout this county, that I need hardly speak of them in detail. To one of them, however, I must refer when I come to speak of antiquities of the Roman period. Of primeval remains, intended originally as places of sepulture, most conspicuous are the cromlechs. In this class of antiquities the county is particularly rich, as regards both their number and the importance of individual examples. The great cromlech at Pentre Ievan, in Kemes, which ranks very high among those which are known to exist, the cromlech at Longhouse in Dewisland, that at Dol Willim (not in Pembrokeshire, indeed, but just beyond the limits of the county), and that at Burton, in Roose, ought to be mentioned specifically. The stone circle is commonly associated with the cromlech, as part of the same arrangement. Antiquities of this class are most abundant in the northern part of the county, in the neighbourhood of the Preselly range, of the Pencaer hills, and the St. David's rocks. Whether this fact is due to the abundance of material, or the comparative absence of cultivation (which in these, as in other cases, tends to the destruction of antiquarian remains), I do not pretend to decide. I learn from a recent number of the "*Archæologia Cambrensis*," that in the particular district in which so many examples of this class survive there also survives a venerable belief that they were intended for sacrificial purposes—in fact, that they were not tombs, but altars. In the region in which they are largely found the *maenhir* is also common. But this is so simple and so obvious a memorial that it is not in all cases necessary to attribute to it any high degree of antiquity. I do not learn that at any place in Pembrokeshire there have been found stones with those mysterious markings, which have so greatly puzzled archaeologists, which appear to be widely diffused through various parts of the world. Of sepulchral remains of another class—barrows, tumuli, *carneddan*, and so forth—I believe there is good store in the county. Two in the immediate neighbourhood, viz., Carew and Norchard Beacons, were opened immediately after the Cambrian meeting in 1851, and the results are given in the "*Archæologia Cambrensis*" of that year. Another, situated on Stackpole Warren, will, it is hoped, be examined during the present meeting. Of ancient roads I have not much to say. One seems to run along the ridge of the Preselly Mountains, and its course is marked in the Ordnance Map. I traced another in the neighbourhood of St. David's, and what I found there may be read in the history of that place.

#### *The Roman Period.*

I have little enough to say about Roman things. You know, I doubt not, the story of a learned topographer who in his great book on Iceland wrote the following pithy chapter under the heading "Of Serpents":—"There are no serpents in Iceland." Perhaps my chapter on Roman antiquities in Pembrokeshire had better have been equally concise and in other respects similar. I do not know that there is any trustworthy evidence that the Romans ever got into Pembrokeshire at all. We find material traces of them in Cardiganshire, and in the upper part of Carmarthenshire; and, although I am not aware that any Roman remains have been found there in modern times, I suppose there is no doubt that Carmarthen occupies the site of a Roman town. But I see no certain evidence of Roman occupation further west than that place. Well, then, what about Menapia, the site of which, or what remains of it, is to be visited by the Association on the 11th inst.? When I last went to look for Menapia, it was supposed to be under I don't know how many feet of blown sand, so I have no doubt it is quite safe, if it ever existed. But what is the evidence of its existence? Richard of Cirencester, or the ingenious person who wrote under that name. On the whole it would seem most likely that the name of Menapia is simply modified from that of Menevia, the Latin name (and no doubt a Latinised form of the ancient Celtic name) of the place of which I have the honour to be bishop. The Ordnance Map finds a place for another station of Richard's—"Ad Vigesium," but does not indicate any actual remains. Nor have I ever seen any trustworthy evidence to show that anything of Roman make has been at any time discovered in the county. What Fenton tells us on this head is vague and uncertain, and is mainly of the nature of hearsay evidence. I do not know whether the point which I am now about to bring forward is of the least value. At a very short dis-

tance from Menevia, or St. David's, there are two small forts, one quadrangular and the other circular, of which the latter seems plainly to be later than, and to have cut into, the former. It was long ago suggested to me by an accomplished archaeologist that the quadrangular fort may have been of Roman origin, and may have been afterwards adopted and adapted by some Celtic chieftain. What this conjecture is worth I leave to be determined by the Association. Indeed, I do not know how far the form of the object in question can be taken as evidence of its date or origin.

#### *Post-Roman Remains.*

I now come to the post-Roman period. By this I mean the interval between the withdrawal of the Roman forces from Britain and the development of the Mediæval system in Church, State, and Art. But this definition must be taken with two or three grains of salt. In the first place, it may very well be, as I have already hinted, that certain so-called primeval antiquities really belong to this period. I do not suppose that this part of Britain was ever thoroughly Romanised, and I do not doubt that in many things the people went on in their own ways all through the Roman occupation, and longer. Very likely some of the hill and cliff forts belong to this time, as, for example, one near St. David's, of which I have just spoken. Leland, in speaking of St. David's, speaks of the "two castles of Boia." One of these is no doubt the rude rampart crowning a steep isolated rock called Clegyr Foia; the circular fort cutting into the quadrangular one (which lies near it) may be the other. But Boia appears in legend as the heathen chieftain who thwarted St. David in his work. The legend may be worthless, or later tradition may have connected it (according to its wont) with a monument of much more ancient date. On the other hand, the tradition may be true, and these remains may have been the work of Boia. Again, there can be little doubt that there was much heathenism in the district after the withdrawal of the Roman power. Before this date Christianity seems to have taken a somewhat feeble hold in the country, and to have chiefly influenced the Roman towns. It was about the sixth century that a rapid and energetic development of Christian life seems to have taken place in Wales, and generally in Western Britain, mainly through the agency of a peculiar monastic system. Now, in the lives of the British saints of this period (which appear to be too unanimous in this respect to be otherwise than trustworthy) Christian teachers are always represented as having to struggle with positive heathenism. Assuming this to be true, the heathen inhabitants of the country, no doubt, went on burying, and perhaps burning, their dead in the old heathen way, so that many places of burial which we consider primeval may have been really of this date. A few years ago I was reopening the parish church of Hasgurd in this county. I was told that the churchyard, which is, if I recollect right, unnecessarily large for the parish now, must have been curtailed, as there were graves to be seen in an adjoining farmyard and field. True enough, there they were; but I do not believe that those graves were ever dug in any Christian churchyard. They were regular kists formed of rude stones. At the same time, I think it likely enough that they were post-Roman. The labour of excavation at this place would surely not be thrown away. The most important and interesting remains of this period are the monumental stones, lettered or unlettered, but manifestly Christian, which abound in this part of the principality, and of which a large collection of drawings is published in Professor Westwood's "*Lapidarium Walli*." I am indebted for much that I am going to say about these to a very valuable paper on the Ilkley crosses in the last number of the *Journal* of this Association by an able archaeologist connected with this country, Mr. J. Romilly Allen. Mr. Allen, in the paper to which I refer, divides the Christian monuments of this country into three periods, to the first of which he gives the name of Early Christian, and fixes its two limits at the landing of Augustine on the one hand, and the Norman Conquest on the other. He further divides this period into two, of which the earlier is characterised by "rough unhewn monoliths, erect, with incised crosses, sometimes accompanied by an inscription in debased Latin capitals or oghams." These he attributes "to the period when paganism was being superseded by the new faith." The monuments of the later period are marked by the peculiar interlaced ornamentation found on what are commonly, but improperly, called Runic crosses, of which we have conspicuous examples at Carew and Nevern in this county. These later monuments are assigned by Mr. Allen to the five centuries preceding the Norman Conquest. If this view is one to be relied upon, I suppose we may regard the earlier and simpler memorials (some of which, by-the-by, may possibly be older than the landing of St. Augustine) as due, like the more ancient inscriptions in the catacombs, to the age in which the Church was struggling for existence in the country, and fighting its way, sometimes through much suffering, to a recognised position; while the art and labour lavished on the more recent monuments mark a time in which the Church was settled, established, and at rest. If this is true, it is impossible to exaggerate the interest attaching to the earlier days of monuments. It is true that the names they record are in most cases otherwise unknown to us, although I believe one or two of them have found a place in the legends and genealogies of the Celtic saints.

Still they remain as tangible memorials of a time of which we have no contemporary record (if we may except the curious document which bears the name of Gildas), and about which nearly all that we can be said to know comes to us in the way of inference from later uncritical legends. Still I would observe this. Mr. Romilly Allen has shown that these rude memorials, which are very numerous in the southern division of the principality, radiated from Ireland as their specific centre. This fact both illustrates and supports what is inferred from other sources as to the reflex influence of Irish Christianity at this period, not only in Britain, but even on the Continent of Europe. It is to monuments of this date that I should especially apply the title of post-Roman. The inscriptions, at least in South Wales (though occasionally either in the ogham character and in a Celtic language, or else bi-literal and bi-lingual), are most commonly in Latin and in debased Roman letters, while the names recorded are very commonly Roman names more or less corrupted. Everything betokens a lingering shadow of Roman influence. In the later monuments, on the other hand, which we may consider transitional, we have a foretaste of Mediæval art. They may be presumed to have been contemporaneous with that earlier and simpler form of Romanesque architecture which is much more common on the Continent than among ourselves, the earlier specimens of which in England may perhaps be found in the work attributed to St. Wilfrid at Hexham and at Ripon, to the later English examples to which we give the name of Anglo-Saxon, and which (to judge from specimens of the style remaining in that country) appears to have obtained to considerable excellence in Ireland. Of architecture of this date there are no existing traces in Pembrokeshire, unless we are to ascribe to it a singular group of crosses inserted in a niche behind the high altar of St. David's Cathedral, and possibly a few stones with interlaced work which have been built up into the central tower. Nor am I aware that any other building in Wales contains even a fragment of such architecture, unless the ornamentation on the tympanum of the doorway in Llanbadarn-fawr Church, Radnorshire, should be thought to belong to it; for there we certainly find in full force and vigour what Mr. Romilly Allen describes as characteristic of the date, namely, "conventional animals with intertwined bodies, limbs, and tails."

#### *St. David's Cathedral.*

I come now to Mediæval architecture, and begin, of course, with sacred buildings. I may safely say that there is no real Norman church architecture in Pembrokeshire, or, with one exception, in the three south-western counties of Wales. The sole exception, so far as I am aware, is the fine chancel arch of St. Clears, in Carmarthenshire. Probably during the period in which this style was in vogue our churches were very poor and small, while the country was unsettled and a battle-ground of races. There is nothing of this date even at St. David's. No doubt the Celtic bishops were content to go on in their own way, and, although the earliest Norman bishops in other sees generally rebuilt their cathedrals in the fashion of the day, perhaps neither Bernard nor David Fitzgerald were quite the men to set about so great a work. But when Peter de Leia came to the see a new architectural period had already dawned, and the great bulk of our cathedral church is built in successive modifications of this transitional style. Of course, it exhibits alterations, additions, and insertions of various dates down to the beginning of the sixteenth century, and its history, as it has to be read in the traces of these numerous changes, presents an interesting, and at the same time a difficult, problem to the archaeologist. But I cannot dwell upon these points in detail at present, nor have I any right to anticipate what will, no doubt, be brought before some of you more fully on the spot. I will only say this, that while the cathedral church of St. David's takes a low rank in point of actual dimensions among the minsters of this country, I know of nothing in the world so impressive. The wild country which surrounds it, the sense of isolation, the neighbourhood of the sea and the consciousness of its being on almost every side of you, the marvellous picturesqueness of the ruined buildings in the midst of which it stands, undoubtedly enhance the influence of the impression which it produces when it is first seen from without. But the effect of the exterior, which must be admitted to depend in some degree upon these accessories, is far less imposing than the first view of the interior on entering by the south porch, above all, in the low light of evening. The complicated richness of the Romanesque mouldings, the deep and solemn colouring of the native stone, the strange and fantastic details of the flat ceiling and its pendants, and (now) the painting, gilding and mosaic dimly visible within the darkened choir, combine to render this one of the most striking architectural views in this country, or anywhere. But, again, I must not anticipate.

#### *Conventual Churches.*

The chief conventual churches in Pembrokeshire, at all events of which any remains exist, are St. Dogmael's, Monkton, Pill, and Haverfordwest Priors. Of these, two only come within the scope of the Association at present, Monkton and Haverfordwest. The former, the nave of which is in use as the parish church, and the choir of which it is intended to restore, is utterly unlike anything I ever saw in the way of proportion. It is a long aisleless choir

attached to a long aisleless nave, and having a large chapel to the north of the choir, forming, however, a distinct building. In fact, it looks like three churches in contact, and perhaps it really was so; for although it is most difficult to say exactly how the opening from the nave into the choir was managed, there are symptoms which incline me to believe that it was little more than a doorway, so that the choir and nave would have the appearance of being (what they no doubt were, as regards their use) two distinct churches. At Haverfordwest the ruins do not give any certain indication of what the church was like; but I should infer from what I have seen that it was a cruciform church of the thirteenth century, certainly without aisles, and probably with a central tower. This was a not uncommon Welsh arrangement for important churches: witness the abbey church of Talley, and the minster of Llanbadarn-fawr, in Cardiganshire. The two most important parish churches in the county, architecturally, are St. Mary's, Haverfordwest, and St. Mary's, Tenby. The former is quite one of the most interesting churches in Wales, and nowhere perhaps in the principality is there better detail. The latter is striking, but of a somewhat unusual type in Wales. Its ground plan and arrangements partly resemble some of the larger Cornish churches.

#### *Pembrokeshire Type of Church.*

None of the churches which I have mentioned, with the single exception of Monkton Priory, exhibit the characteristic features of Pembrokeshire parish churches. This singular type is found, as a rule, only within the English-speaking districts of the county, and I believe no specimens of it are found within those districts on the shores of St. Bride's Bay. Their main features are tall and slender towers, generally diminishing as they rise, a general rudeness of masonry, and internally much vaulting, with side chapels and squints, and many holes and corners, and a general effect of cavern-like obscurity. Of these churches I do not know that a more typical example can be found than Manorbier in this neighbourhood. They are very peculiar, but more in their general tone and effect than in any particular details. I know nothing like them anywhere else. Unhappily—I am speaking now as an archaeologist, not as a bishop—the hand of the restorer has been somewhat busy with them, and it is not always easy to make out how much one is to believe of what one sees. I ought, in passing, to call attention to one very beautiful parish church in this neighbourhood, which is not at all of the Pembrokeshire type. I mean Carew, where it is pretty easy to recognise the hand of my predecessor, Bishop Henry Gower.

#### *Castles.*

Then we come to another class of antiquities, both numerous and conspicuous in this district. Pembrokeshire is a perfect paradise of castles. Not to mention others, three remarkably interesting ones are within easy reach of this place—Manorbier, which is, perhaps, the most picturesque of the Pembrokeshire castles, especially when looked at in connection with its surroundings. Carew, which is the most complete, and which, like Kenilworth, contains portions which mark the castellated manor-house rather than the castle, properly so called, and Pembroke, the queen of South Welsh castles, and certainly one of the most impressive masses of building I have ever seen. One more castle must be specially mentioned, both on account of its inherent interest and because some of those who hear me are to pay a visit to it next week. I mean Picton, which presents the unusual feature of a mediæval fortress (for it was a real fortress, and not a mere castellated manor-house) remaining in the occupation of the ancient family which owned it down to the present time. Considering that it is at this time a convenient mansion, to which a large addition was made early in the present century, there has been far less destruction of its original features than could have been expected to be the case.

#### *The Bishop's Palace.*

Of domestic remains of the Middle Ages there are, in addition to minor buildings and fragments to which I need not now refer, but which are numerous, two great habitations of my predecessors, one undoubtedly, and the other (in part at least) very probably, the work of Bishop Henry Gower. The palace at St. David's is quite one of the best pieces of Mediæval domestic architecture in the kingdom. Its style and arrangements are peculiar to itself and to two other buildings commonly attributed to the same prelate, while it presents to the archaeologist the unusual spectacle of a great Mediæval house, partially ruined indeed, but otherwise left very much as it was built. It dates from the early part of the fourteenth century, and exhibits few, if any, traces of later addition or change. I suspect the secret of this to have been that my predecessors never found St. David's a convenient, or perhaps a very comfortable, place to live at, so that they did not care to adapt it to the requirements of their own times. I think it likely that it was largely used during the first two centuries of its existence for receiving the numerous pilgrims who came to St. David's. Soon after the Reformation it fell into decay. Undoubtedly the bishops' favourite place of residence, when they were in the diocese at all, was Lamphey, to which I have already alluded, though not by name. Whether this is to be regarded as an earlier attempt in

the style which culminated in the St. David's Palace, or as a feeble imitation of it, has been disputed, but I will not now stop to consider. All I can say is that it is very like and greatly inferior to it. This mention of episcopal houses leads me to notice the bishops' baronial castle of Llawhaden, which I hope some of you will see next week. If you have reason to find fault with its present condition, please to remember that it does not belong to me, but to the Ecclesiastical Commissioners for England.

#### *The Welsh Marches.*

I must at this point bring to a close my remarks upon the material and tangible antiquities of the county. But there are one or two other points which deserve notice. First, there was perhaps no other part of the kingdom in which the feudal system was more thoroughly developed in the Middle Ages than was the case in Pembrokeshire. The great distance of the district from the central authority, and the neighbourhood of a hostile and restless race, gave the local lords of the soil a position far more nearly resembling that which their compeers occupied in France and Germany than was generally to be found elsewhere in England, except (from similar causes) in the north. The Earldom of Pembroke was, in fact, a palatinate. The Lordship of Kemes remains to this day, perhaps the best specimen of a Lordship Marcher, although it is, of course, shorn of much of the power with which its lords were anciently invested; while within his Barony of Llawhaden and his Lordship of Dewisland the Bishop of St. David's occupied a position analogous to that of his brethren at Durham and at Ely. A carefully-written history of mediæval Pembrokeshire would be a work full of intense historical and even romantic interest; and the interest would be largely enhanced by the fact that two races different in origin, language, feeling, and traditions were found here, as they are still found, side by side. One cannot help regretting that no work of fiction by a master hand like that of Scott has ever had its scene laid in this county. That great writer of romance did, indeed, attempt to describe the social condition of the Welsh marches, but the sketch was a slight one and the results were not very satisfactory; while he placed on the eastern border of the Principality the curious settlement which is recorded to have been planted in the district in which we are now gathered. I speak, of course, of the Flemings; and, to judge from my experience on a former occasion, I do not doubt that we shall hear enough of the Flemings before we separate. Perhaps I may be allowed to say a little about them now.

#### *The Anglian Settlement.*

A very slight notice of this settlement has been developed by the antiquarian imagination in a much greater matter than we can find it very easy to accept as historical. The establishment of a certain number of strangers of Teutonic blood and speech has been commonly regarded as a sufficient explanation of the curious phenomenon which here presents itself to the ethnologist, namely, the prevalence of the English language throughout the south-western portion of this county, not at present only, but, as is plain from the names of places, for centuries past. Curiously enough, another, but a smaller, district which occupies a similar position, and which, like the Anglia Trans-Walliana of Pembrokeshire, is cut off from England by the Welsh race, is similarly supposed to have been colonised by Flemings, without any evidence, so far as I know, that any of that race ever established themselves there. I speak of the peninsula of Gower, in which a supposed Flemish colony is, I believe, merely an inference from the alleged existence of such a colony in Pembrokeshire. I am inclined to think that the Flemish settlement in Pembrokeshire was by no means large enough to cover the facts before us, while I have no reason to believe that any such settlement was made in Gowerland at all. In each case the country was thoroughly conquered and settled by invaders from England, being doubtless attacked from the side of the sea; and the old inhabitants, who, to judge from the names of places in both districts, seem long to have maintained a separate existence in the midst of their conquerors, were at length absorbed and assimilated. The Pembrokeshire Anglia Trans-Walliana was a district nearly resembling the Irish Pale, and, like that, was known as the "Englishry." It may be a question, however, whether the way had not been paved for this conquest, settlement, and ultimate assimilation of the original inhabitants by Scandinavian settlements on the coast and on the shores of Milford Haven. We read much in the chronicles of St. David of incursions of Danes and Northmen, and though there is no direct historical evidence of anything beyond passing invasions, the names of some places in Pembrokeshire seem to point to something like a settled occupation at certain points. Skokholm and Skomar, Haverford and Milford, Fishguard and Hasguard, all look more or less that way. Although it is said to be the corruption of a Welsh name, I have great doubts whether Tenby is not really Scandinavian; while that of Freystrop, if not of northern origin, which it very well may be, must surely date from a time when the Teutonic people who built or occupied the village worshipped the gods of their heathen forefathers, which certainly cannot be supposed of the Flemish settlers of the twelfth century. I throw out these suggestions for the consideration of the Association at its present meeting.

And now I must draw what I have had to say to a close. I

am conscious of having left many *lacunæ*, and of having, in all probability, made several mistakes. But you must take these remarks as a slight and hasty sketch of the antiquities of the district, and nothing more. It only remains for me to tender to the members of the Association my most grateful thanks for the conspicuous honour which has been done to me in their choice of a president for this year, and at the same time to wish them a pleasant, prosperous, and profitable meeting.

## HINDRANCES TO THE PROGRESS OF ART SCHOOLS.\*

WITH many admirable exceptions, the influence of those who derive direct and immediate advantage from improvements in design and art workmanship have not been favourable to progress, especially when the schools were in their infancy, needing all the support that could be given to them. The establishment in this country of the art of design as a distinct pursuit has necessarily brought about a change in the attitude of manufacturers, but they are often indifferent to art except as a saleable commodity, even where abundant means and the prestige of past reputation for honest workmanship would justify higher and bolder aims; and the too common desire to repress all individuality in designers and art-workmen is greatly to be regretted. Many excellent drawings are completely spoilt by alteration or combination, simply in order that designers may not be able to lay claim to them, and occasionally the process is so effective that only *disjecta membra* can be identified. Many illustrations might be given of the want of interest displayed by manufacturers, but one instance must suffice. Not long ago, an artisan student at a school of art designed a fabric, and asked his employers to weave a portion for a competition. The request was refused, whereupon he took his design to another firm, paid for its production, gained the sought-for prize as well as a prize from South Kensington, and is now employed as a designer to the manufacturers who wove the piece. Had he been less determined he might still have been serving his former employers as a weaver; had they been more liberal-minded they might still have enjoyed the advantage and profit accruing from the exercise of skill in the development of which they refused to assist. As an example of the ignorance to be encountered, it may be stated that not long ago an ironfounder, speaking at a public meeting on the superiority of the nineteenth century over any previous age, said that his men could put up a pair of gates in as many days as it took years to complete the Ghiberti gates! Nothing less than Sydney Smith's "surgical operation" would suffice to get any idea of art into the head of a man of this stamp; and though the case is doubtless an exceptional one, the feeling of many manufacturers towards art in its relation to their productions is certainly very capable of elevation.

Although the advance already made receives cordial recognition abroad, and we are gradually becoming alive to the truth that foreign work in design or execution is not necessarily in admirable taste, hankering after continental "novelties" is by no means extinct amongst us, and receives no little encouragement from the manufacturers themselves. Sir Philip Owen, in an address recently delivered, said that some few years ago he presented the prizes at a school of art, and one of the recipients was a designer, who entered the service of a Parisian firm at a salary of 400*l.* a year. While he was at home this young man made a great many designs, without finding any one who would take them up; but as soon as he went to Paris the manufacturers followed him there, and paid him ten times the amount they would have had to give for his designs in England. From the first establishment of the schools to the present time—though in a gradually decreasing proportion—manufacturers have spent much money on foreign designs, many of them done by English hands, which might have been more economically laid out at home, both in a personal and in a national sense; and several instances could be mentioned in which artists of very high merit, unable to find employment in the home market, have attained abroad a position there recognised as eminent.

Ungenerous disparagement of the schools of art and of their teaching has also had its hindering effects. In spite of abounding evidence to the contrary, men are sometimes heard to declare that the schools have failed in their object, and that manufacturers in want of designers apply in vain for qualified and capable students. Cases are, however, known in which fabricators of such statements have persistently rejected designers of ability who have applied to them for employment until they have at last been brought to admit that they had no such requirements. And where designs have been submitted for acceptance it has occasionally been ascertained, by means of precautions previously taken, that those who rejected them as valueless have, nevertheless, been mean enough to take tracings of them before sending them

\* From the "Handbook on Art Schools." By Mr. J. C. L. Sparkes.

back. Therefore, when disparaging statements are made respecting the schools and their teaching, the public will do well to contrast them with the incontrovertible evidence afforded by their marked effects on local industries and art manufactures generally, as they are practically exemplified in the admirable display to be seen in the gallery devoted to the work of the schools in the International Health Exhibition.

It may be hoped, however, that detractors and opponents are in a constantly decreasing minority. In many towns the beneficial operation of schools of art is warmly acknowledged and encouraged, both by manufacturers and by the general public. Many firms insist on the attendance of their apprentices at the evening classes and make this a condition of their indentures, sometimes paying the school-fees, and contributing also to the local subscription in aid of its support. Such subscriptions are, however, by no means so general or so liberal as they ought to be. It has been shown that in some places the inhabitants have been most generous in providing for the erection of schools of art, museums, &c., and in many others, especially the smaller towns, the local subscriptions are fairly liberal, sometimes approaching the amount of the aid received from Government; but there are large towns in which not a single penny is subscribed even for local prizes, which are occasionally provided by the art master out of his own stipend, and in others the amount subscribed is ridiculously small considering the wealth of the locality and the dependence of its staple industry on the education of the designer and art workman. Local prizes are greatly needed as an inducement to exertion, especially in schools that have little or no chance of success in the national competition. The influence of this annual trial of strength is variously regarded, the successful schools being warm in praise of its invigorating influence, whilst those who win no share in the honours bestowed have a tendency to underrate their worth. But there can be no doubt of the advantages of a general competition of this kind, and any attempt to extend the number of prizes, or to make them more easy of attainment, would necessarily have the effect of lowering their value as marks of distinction. It might, however, be advisable to extend the scope of departmental reward, so as to bring within its range the work of schools which are practically outside the pale of the national competition. But it should be the business of each particular locality to recognise and reward the merit of students, in all stages of their training. The value of competition, as a stimulus to application, cannot well be over-estimated, and local prizes keep alive the interest of students, especially of the younger ones, who have to wait a long time for success in the higher grades of their art. Liberal encouragement is therefore of much importance, and the public would do well to bear in mind the words of the wisest of men:—"There is that scattereth, and yet increaseth; and there is that withholdeth more than is meet, but it tendeth to poverty."

In addition to those already mentioned, there are various minor hindrances that may be briefly glanced at, such as the vicious and vulgar admiration for what looks "rich" and costly, rather than for what is artistic; the extravagant expectations and consequent disappointment of people who look for the prompt conversion of their children into draughtsmen and painters; the absence of any definite object in towns where design is not required for the local industries; and the lack of sympathy experienced in some places by teachers, who long in vain for countenance and encouragement in their work. There are also internal hindrances, amongst which may be admitted mistakes in central government and local control, to be obviated only by the corrective influences of time and experience, which are not rapid in their action on departmental arrangements; the tendency of students to adopt fine art as a profession, either as a ready means of earning a livelihood, or under the mistaken supposition that it is better to be an indifferent "artist" than a good designer or art-workman; incompetence and want of tact on the part of teachers—for in art, as in scholarship, though men of high attainments are comparatively abundant, really good teachers are rare; the insufficiency or unsuitability of school buildings, which in some places are greatly in need of improvement; the too general avoidance of time studies in the provincial schools, notwithstanding their paramount value in the rapid development of ability, as distinguished from elaborate manipulation; and the inability of working students to attend the classes, except at the end of a hard day's labour, when they are naturally inclined to devote their scanty leisure to recreation, rather than to study. Many have to walk long distances to and fro, and though the disciplinary advantages of self-denial are undoubted, their studies might be greatly facilitated by some relaxation of the hours of labour, and it is hoped that the inclination to concede this will become increasingly general. The conventional difference which exists in this country between the social position of the pictorial artist and that of the designer will doubtless be diminished as the art of the latter becomes better appreciated. In France there is a much nearer approximation of the one to the other, and those who confine their ideas of art to that which is known as fine art should be reminded that Raphael and Albert Dürer, Holbein, and Cellini, and Flaxman, are inseparably associated with the art whose dignity and importance they are so apt to underrate. Certainly no designer who aspires to be regarded as a

true artist should be ashamed of his vocation, with such imperishable names as these to point the way to excellence.

There are, however, designers and designers, and their earnings have necessarily a very wide range, according to the nature of the industry to which their art is applied. There is in our manufactures scope for the exercise of all degrees of artistic skill, which may be applied to the simple sprig that adorns a cotton print—such as the famous parsley leaf so closely associated with the fortunes of the Peel family—or to some beautiful and elaborate work of art which will claim the admiration of all time. In the lace trade there are designers who receive salaries ranging from 500*l.* to 700*l.*, and even 1,000*l.* a year, whilst others, working independently for any firm that chooses to employ them, also make large incomes by their skill. Good textile designers, even without marked genius, command from 100*l.* to 300*l.* a year, whilst the salaries of others of inferior mark range as low as 70*l.* The earnings of designers of wall papers vary from 3*l.* to as much as 20*l.* a week, but this maximum is of course but rarely touched. In calico printing and many other trades the salaries paid are by no means high, generally about 2*l.* a week, but it is difficult to quote figures, which must be altogether dependent on the nature of the work and the ability of the designer, and, in a measure, on his quickness also. Unfortunately even capable designers frequently find encouragement in their art so slow and precarious that they are compelled to have recourse to teaching, picture-making, or some other means of providing for their necessities; and cessation of employment in some departments of art-manufacture not unfrequently results from their own success, for (in textiles especially) the necessity for fresh designs is in an inverse ratio to their acceptability; manufacturers are of course only too glad to keep their looms engaged in the execution of a particular pattern, until the demand for its production ceases. The deficient cultivation of the purchasing public is still much felt, not only by manufacturers, who frequently meet with a slow demand for their most artistic productions, and are thus discouraged in their attempts to lead the public taste, but also by the more capable designers, who find themselves in advance of the market, unable to obtain the employment for which they are best fitted.

At a time when most strenuous efforts are being made in foreign countries to bring art-teaching to the highest pitch of excellence, it is more than ever desirable that no opportunity should be neglected, or rather, that opportunities should be sought, for the improvement of our systems of instruction and management. Many masters of schools of art occupy a position of isolation, the narrowness of which has its effects on their work; and, as a counteracting influence, it would be very advantageous if arrangements could be made so that they might have an opportunity to spend a week in London during the summer holidays, in order to take part in an annual conference with the officials of the department on subjects relating to the work of the schools, and at the same time gather reciprocal advantages from renewed intercourse with old fellow-students. Might it not be possible, also, to assist a certain number of deserving masters to enlarge their experiences by occasional visits to the schools of France, Belgium, &c.?

## EXHIBITION AT BRISTOL.

AN industrial and fine art exhibition for the counties of Gloucester and Somerset was opened on Tuesday at the exhibition buildings, Rifle Drill Hall, Queen's Road, Bristol, in aid of the funds of Bristol University College, founded in 1876. The college has no endowment, and is dependent to a great extent for its existence on local beneficence. It proposes not only to supply for persons of either sex above the ordinary school age the means of continuing their studies in science, language, history, and literature, but particularly to afford appropriate instruction in those branches of applied science which are more nearly connected with the arts and manufactures. After using temporary buildings for some four or five years, the promoters commenced their permanent structure in Tyndall Park, Clifton, upon the two completed sections of which about 15,000*l.* have been spent, but the estimated cost of the whole structure is 50,000*l.* The annual subscriptions to the sustentation fund at present amount to 1,100*l.*; the total receipts from students last session were 2,200*l.* The annual expenditure is 4,500*l.*, and there is consequently a deficit. The average number of students who have attended the college during the last six years exceeds 510, and the average number of classes attended has been 820. The Industrial and Art Exhibition, which is divided into three sections, occupies in all 35,000 superficial feet of space, exclusive of several courts. Section 1.—Fine Arts. Division A includes paintings, drawings, statuary, bronzes, mosaics, and art designs in the precious metals and gems; division B, architectural designs and sketches, engravings, etchings, photographs, tapestries, art needlework, rare carvings in wood and ivory, paintings on glass, ivory, and porcelain, and designs for art manufactures. Section 2 comprises machinery in motion, and illustrations of mode of manufacture. Section 3 embraces specimens of industries and natural productions, models, and mechanical designs. There are

about 120 exhibitors, mostly local firms, in the industrial exhibits and machinery in motion.

In the large Drill Hall the cabinet manufacturers of Bristol and Bath cover by far the largest space, and artistic cabinet work, both in costly and inexpensive material, is displayed in suites of rooms temporarily constructed, and presenting all the appearance of completely furnished apartments. Examples of the old stoneware produced in Bristol are shown. There are about one hundred and fifty specimens of the Elton ware from Sir Edmund Elton's Sunflower Pottery established within the past two or three years at Clevedon. Every article being hand-made, the variety of design is particularly marked.

The fine arts department, a distinctive feature of the exhibition, contains a magnificent collection of valuable pictures numbering about five hundred contributions by owners from their private collections, the Mayor of Bristol being a large contributor. These include *The Pool of Bethesda*, by Mr. E. Long, R.A., a couple of paintings by Mr. John Brett, A.R.A., a large number of works of Syer, Branwhite, and Müller, and the following artists of distinction are also strongly represented:—S. B. Jackson, C. Knight, Hopkins, D. Cox, Leitch, F. Danby, A.R.A., J. Curnock, J. B. Pyne, Faulkner Poole, R.A., Britton Willis, Orchardson, R.A., M'Whirter, B. W. Leader, Yeames, R.A., Sidney Cooper, R.A., J. Hardy, Briton Riviere, R.A., W. P. Frith, R.A., J. A. Stanfield, R.A., Sir A. W. Callcott, R.A., Frank Holl, R.A., and J. E. Millais, R.A. The following articles are exhibited on loan from the South Kensington Museum:—Electrotypes, European porcelain, enamels, jewellery, glass, and goldsmiths' work, Spanish and Italian embroidery, Japanese and Chinese pottery, bronzes, and enamels. The Bristol Corporation plate is also a prominent object of interest.

### ELECTRIC LIGHTING OF HOUSES.

A PAPER on "Electric Lighting of Houses" was read by Mr. W. H. Preece at the meeting of the British Association at Montreal. The author described the fitting up of his own house, which has been done not so much to determine the cost as to discover faults, troubles, nuisances, and the amount of supervision necessary to keep it going. His house is really gas-lighted, but the gas is burnt in the garden where he extracts that which he wanted—light, and discharges harmlessly into the air what he does not want—poison. The gas-engine, dynamo, and fittings were described. He uses secondary batteries, of which he expressed a very favourable opinion. He has constant night and day service, and can illuminate the house at any moment in an instant. Even his daughter's doll-house has its four rooms lighted by little fairy lamps. The use of 30-volt pressure renders safety from shock or fire certain. He carries the light throughout his garden, and can visit his greenhouses any hour of the night. He can even light a cigarette by electricity. Mr. Preece regards electric lighting still as a luxury, and estimates the cost of fitting a house like his at 7*l.* 10*s.* per lamp. He does not expect to consume more gas than hitherto, while he has filtered light and purified air. The advantages are the steadiness and comfort of the light, the durability of the decorations, the absence of heat and destructive gases, pure air, and longer life to all using electric light. Its economy consists in being used only when and where wanted. If it costs twice or thrice what gas does it need only be used half or one-third the time; gas is needlessly wasteful. He spoke hopefully of the future of electric lighting, and believed every one would have it if electricity were supplied at our doors. This in England was rendered almost impossible by the objectionable Act of 1882, which should be repealed or considerably modified.

### THE ROYAL ARMOURY OF MADRID.

A FEW weeks since, says a correspondent of the *Times*, the news arrived of a fire having occurred on the roof of the Royal Museum of Arms and Armour at Madrid—news which startled every historian, archæologist, and lover of the fine arts to whom by hearsay or by sight that invaluable collection was known. Strangely enough, beyond the mere notice of the accident, scarcely any further information has been published in England on the subject, which, as far as the general reading public is concerned, has almost faded out of memory. Not so with those who know the priceless gems of that most rich museum, taking rank as it does with the armouries of Vienna, Dresden, Turin, and Paris.

In a long room on the first floor of an isolated portion of the ancient palace, and facing the courtyard of the new, these treasures had been gathered together, and were admirably mounted and arranged under the constant and untiring care of a true art lover, the Conde de Valencia de Don Juan. Here were grouped the numerous and remarkably fine suits of armour for the tournament, for war, or for mere pomp, which actually belonged to and had been used by the Emperor Charles V., after whose death the other moiety of the Imperial armoury passed to the Hapsburgs, and is

now preserved at the Vienna Arsenal. Some 20 suits remain at Madrid, among which are some of the finest examples of the Flemish, the Italian, the German, and the Spanish armourer's art, variously enriched by inlay of silver and gold, by graving, and by incomparable *repoussée*. One of the helmets (which has been estimated by good authority as likely to realise at least 75,000 frs. at the Rue Drouot or Christie's) and some shields are quite unrivalled for their admirable design and the perfection of their workmanship. Then in sequence were arranged the splendid suits and weapons which belonged to Philip II., to Don Carlos, to Philip III., and Philip IV., trophies of Lepanto, numberless historic swords, such as that of Francis I., of "el Gran Capitan," Fernandez Cortez, Pizarro, &c., many of which are of surprising beauty. For years, after the Spanish fashion, these arms lay here and there neglected in various palaces, &c., exposed to the chances of rust, rough usage, or robbery, until of late, under the intelligent initiative and at the private expense (some 250,000 frs.) of King Alfonso XII. and the painstaking assiduity of a true connoisseur, the collection was barely finished in arrangement when this disastrous fire has thrown all into a second chaos. The effect of that long room, filled with mounted warriors and wearers on foot of these rich suits, was very striking; but that general effect was soon forgotten in the examination of the lovely details of ornamentation which covered the surface of so many of the choicer arms. The "dummy" men and horses on which they were mounted, some portraying the features of those monarchs whose steel shells they bore, were richly caparisoned and decked in costly stuffs of the period of the armour, and copying, as far as could be, the costumes represented in painted portraits of their time; all had been directed by high intelligence. Such was this rich treasure-house when visited a short time since by the writer of this article. By great good fortune the manuscript illustrated catalogue made by order of Charles V. existed, and was the foundation for recognition and classification of various important pieces. Contemporary portraits at the Prado and elsewhere also helped in the identification.

On July 10, some short time before midnight, the northern angle of the roof was seen to be on fire. There, in the very centre of the capital, within full view of the Palace Guard (for the building formed one side of the quadrangle), one would have supposed that in a few minutes every sign of fire would have been extinguished, the more so as the building was known to contain so many objects of incomparable value. Yet a precious hour was lost, during which not one bucket of water was thrown, not one fire-engine brought into service. The Spaniards are personally courageous, and those who went to the rescue risked their lives in the endeavour to save the arms. One narrow staircase only existed, and by this and by the windows the arms and armour from the long gallery were hurled pell-mell to the crowd below. But soon the smoke and fire became too strong, and suffocation threatened those engaged in the building; the roof frame was burnt through and threatened to fall among the workers, and soon what remained of this most noble armoury was buried among the burning and smoking fragments of the fallen roof. The loving, careful work of years and priceless treasure was irrecoverably lost for want of a few gallons of water and a handy pump. Thanks, however, to those brave men, the more precious objects of the collection have been saved—many much damaged, it is true, but not much hopelessly. Some of the choicest armour and historical suits and swords, the gold Visigothic crowns, some of the banners from Lepanto, and that most precious illustrated manuscript catalogue of Charles V. referred to above are among the salvage. But the extent of losses cannot yet be known. Nearly all the banners, all the rich and precious ancient stuffs used for clothing the mannequins, all the saddle-cloths, housings, and lambrequines, and the *chaises à porteurs* used by Charles V. were burned.

There are some few learned and scientific men at Madrid, and some who love art and antiquity, to whom the rich Gallery of the Prado, the unfortunate Armeria, and other museums of the city are sources of pride and intellectual enjoyment; but, unfortunately, such men are lost in the crowd of politicians, for politics in Spain are the mania of the day. Nevertheless, the emotion at the news of the catastrophe was great, and the Minister of the Interior was questioned upon the matter and upon the existing (or rather non-existing) arrangements for the security of such collections of art and public buildings as the Gallery of the Prado, the Academy of St. Ferdinand, the Archæological Museum, the Royal Library, the Palace, &c.; and the inadequacy and bad organisation of the fire-brigade was referred to. One would have expected that the Deputies and Senators of Spain would have immediately insisted on a proper inquiry being made, with the view of efficiently reorganising the corps of Pompiers and perfecting their engines and apparatus. Not so. The Minister of the Interior calmly rises in the Senate on July 11 to declare "that the service for the fire-engines of Madrid, say what they may, was far superior to that of most of the capitals of Europe," upon which the subject drops, and all-absorbing political discussion continues its usual endless course.

Here are some few of the consequences of Spanish negligence. To say nothing of the sale of national works of art and archives by Communes, and from churches, convents, &c., and of grand

heirlooms and the like, let us see what has been lost by fire. In 1604 the Palace of the Prado was burnt, and with it some forty *chefs d'œuvres* by Titian, Antonio Moro, Coello, and others; the inventory of these lost historical portraits, &c., still exists. In 1734 the tower of the ancient Alcazar, the Palace of Charles V. and of Philip II., on the site of which now stands the present royal palace. A few years since the Escorial took fire in the roof of the Library, and some hundreds of manuscripts, &c., were destroyed or injured. The Alcazar of Toledo and that of Segovia were burned, and nothing saved. At the Royal Palace, in Madrid, where six hundred magnificent tapestries are stored and other precious objects; at the Picture Gallery of the Prado; at that of St. Ferdinand; at the National Library; at the Archæological Museum—there are neither a station of the fire brigade, nor water conduits, nor tanks, nor even buckets. Lightning conductors are rare and ill-constructed, but the cigarette is in every mouth. During winter braziers inadequately warm the rooms, and petroleum lamps are in use, for in many of such buildings the numerous keepers and their families are heedlessly lodged. No telegraphic system is at hand to raise alarm, nor do the keepers make their nightly round.

## THE GEOLOGICAL SURVEY OF THE UNITED KINGDOM.

A PAPER on the "National Geological Surveys of Europe" was read at the meeting of the British Association at Montreal. It stated that in England the foundations of the survey, and, in fact, of all detailed field geology, were laid by private workers, and a very large proportion of English geological literature has always come from them. On the Continent this has rarely been so; nearly all the surveys are directly due to the Governments, and much of the geological literature comes from those connected with the surveys, or from official mining engineers. There, also, many professors of geology are connected with the surveys; this is not now the case in England, although many of its professors have at one time served on the staff. In fact, at the present time the Geological Survey and Cambridge University almost divide between them the active teaching power of geology in England. The publications of the English Survey are confined to questions relating to its work and progress; but this is not always the case abroad. The staffs of the Austrian and Prussian Surveys have always been active in working at the geology of districts outside their own special areas, which are by no means small, and the results are given in the official publications of those surveys. The best work of late years relating to the geology of Turkey and Greece has been done by officers of the Austrian Survey. The most interesting part of Mr. Topley's report is that which relates to the geological survey of the United Kingdom. The founder of this survey was H. T. de la Beche, who before 1832 had coloured geologically the Ordnance one-inch maps of the South-West of England. In that year a small grant was made by the Government towards the cost of publishing these maps by the Ordnance Survey, but De la Beche also contributed money for the purpose. Subsequently De la Beche was definitely appointed to make a geological survey, under the direction of General Colby, then the head of the Ordnance Survey. The first result of this was the publication of the "Report on the Geology of Devon, Cornwall, and West Somerset," 1839, with the one-inch maps of the district. About 1832 other geologists were surveying various districts upon the one-inch maps of the Ordnance Survey—William Smith in many parts, W. Lonsdale near Bath, H. Maclauchlan and J. R. Wright, both of the Ordnance Survey, the Forest of Dean and near Ludlow respectively, W. Logan in South Wales. Some of this information, notably Logan's, was incorporated in the official geological maps. In 1845 the Geological Survey was detached from the Ordnance Survey and was placed under the Woods and Works; in 1854 it became a branch of the Department of Science and Art. From about the year 1832 some officers of the Ordnance Survey in the north of Ireland collected geological information, which was completed and published by Captain J. E. Portlock in 1843. The geological survey of Ireland was commenced in 1845, with Captain H. James as director, the subsequent directors being T. Oldham in 1845; J. B. Jukes, 1850; E. Hull, 1869. The survey of Scotland was commenced in 1854, and was made a distinct branch of the geological survey in 1867, with Arch. Geikie as director, succeeded in 1882 by H. H. Howell. England, the original home of the survey, was presided over by De la Beche as director till 1845, when A. C. Ramsay became director. He was succeeded in 1872 by H. W. Bristow, now the senior director. The dates of appointment of the directors-general are—H. de la Beche, 1845; Sir R. I. Murchison, 1855; A. C. Ramsay, 1872; Arch. Geikie, 1881. Until 1845 the survey was known as that of Great Britain; when the survey of Ireland was commenced the original name was confined to that of Great Britain proper, the entire survey being called that of the United Kingdom. In 1877 the title of Great Britain was discontinued entirely, this survey being divided into those of England and Wales and Scotland. The total number of the staff of the Geological Survey is now fifty-

seven, distributed as follows:—One director-general, three directors, three district surveyors, fourteen geologists, twenty-five assistant geologists, four naturalists and palæontologists, four fossil collectors, three general assistants. The survey of the greater part of England has been done on the one-inch ordnance maps (1 : 63,860). In the north of England the six-inch maps (1 : 10,560) have been used, and much of the ground has been published on this scale. In the south of Scotland the six-inch maps have been used; but in the north of Scotland the survey will be mainly on the one-inch scale. In Ireland the six-inch maps have always been employed for field work. In Ireland the drift has always been shown upon the one-inch maps by "stippling." Originally no glacial drift was shown upon the English maps; but in 1871 the publication of drift maps was commenced, and two editions of many of the maps are now issued—solid and drift. In the east of England only the drift maps are issued, very little being here known of the solid geology. At the end of 1883 the field survey of the original one-inch map of England and Wales was completed; the survey of the drifts over the areas over which these are not yet mapped has been commenced. In Ireland and Scotland there is only one system of numbering the maps. In England some maps are in sheets, some are divided into quarter-sheets. In the new maps of the Ordnance Survey the system of dividing into quarter-sheets will be discontinued. The maps and their divisions in the north of England are the same in the old and the new series, the numbering only being different; but in the south of England there is no relation between the boundaries of the old and the new maps. In addition to the maps there are "Horizontal Sections," on the scale (for heights and distances) of six inches to a mile. These are published at 5s. each; many have "Explanations," price 2d. each. The details of coal measures, cliff sections, &c., are given on sheets of "Vertical Sections," 3s. 6d. each. An "Index Map," scale four miles to the inch (1 : 253,440), has been published of Wales and the adjacent districts, in six sheets, price 3s. 6d. each. An index map of the whole of England and Wales upon the same scale is now in progress. In all maps of the United Kingdom the meridian is Greenwich. The publication of the maps of England dates from about 1839, those of Ireland from 1855, of Scotland from 1859. The number of maps and sections published is shown in the following table:—

	England and Wales.	Ireland.	Scotland.	Total.
1-inch map (1 : 63,860) (sheets or quarter sheets in England and Wales)	244	180	33	457
Solid . . . . . 183				
Drift edition of solid map 49				
Drift only . . . 12				
6-inch maps (1 : 10,560) . . . . .	216	10	128	354
Horizontal sections . . . . .	129	30	9	168
Vertical sections . . . . .	69	1	7	77
Total . . . . .	658	221	177	1,056

The prices of the one-inch maps are from 1s. 6d. to 8s. 6d. for England (a few detailed drift maps at higher prices); 1s. 6d. to 3s. for Ireland; 4s. to 6s. for Scotland; of the six-inch maps, 4s. to 6s. The "Memoirs" of the Geological Survey date from 1845. Four volumes were consecutively numbered; vol. 1 and vol. 2 (in two parts) contain several papers. The other two volumes and all later "Memoirs" are each confined to one subject or district. There are twenty-four volumes in all. Memoirs or explanations of sheets of the map have been issued since 1859. Those published are—for England, 49; Ireland, 92; Scotland, 17. British fossils are described in "Decades" (thirteen published, from 1849) and "Monographs" (four published, from 1859). "Mineral Statistics" have been published annually from 1853 to 1882, but in 1883 the Mining Record Office, in which these were prepared, was removed to the Home Office, and the statistics will in future be issued as parts of the reports of the Inspectors of Mines. No official general map has been issued by the survey, but the following maps, on scales varying from 7 to 11½ miles to the inch, have been published by the directors of the respective surveys. They are reductions of survey work to date:—British Islands, by A. C. Ramsay, 1878; England and Wales, by A. C. Ramsay, 4th edition, 1879; Ireland, by J. B. Jukes, 1867; Ireland, by E. Hull, 1878; Scotland, by A. Geikie, 1876.

**Frickleton, near Preston.**—Memorial-stones of a new Wesleyan chapel were laid on Saturday last, and a new Sunday-school in connection with this chapel was opened on Sunday. The chapel will accommodate 275 worshippers, and the style adopted is the English Renaissance, the materials being patent bricks and Longridge stone. The entire cost will be about 1,500l. The architect is Mr. David Grant, M.S.A., of Preston.

## NOTES AND COMMENTS.

THE annual report on the London water supply, which Messrs. CROOKES, ODLING & MEYMOTT TIDY have prepared, appears to prove that the water was less impure in 1883 than in previous years. The proportion of samples found to be bright, clear, and well-filtered amounted to 91.4 per cent. in 1881, to 97.6 per cent. in 1882, and to 98.3 per cent. during last year. The proportion of samples free from recognisable ammonia amounted in 1881 to 60.6 per cent., in 1882 to 70.9 per cent., and in 1883 to 82.7 per cent. of the whole. It has also been ascertained that there is a gradual yearly diminution in the quantity of organic matter present in the water that is derived from the Thames. The improvement is attributed in a great measure to the efforts made by the water companies to improve their filtration and subsidence processes and arrangements.

Two of the best of the Blenheim pictures have been saved from enriching the Berlin Gallery. On Monday last Mr. Justice CHITTY made an order sanctioning sales of the *Madonna Ansidei*, by RAPHAEL, for 70,000*l.*, and the equestrian picture of *King Charles I.*, by VANDYCK, for 17,500*l.*, to the Trustees of the National Gallery. Two pictures by RUBENS, one of himself and his second wife, the other of his second wife and her page, which would have been desirable acquisitions to the National Gallery, were sold for 52,500*l.*, but the name of the purchaser was not disclosed. Another picture at Blenheim, the *Mater Dolorosa*, by CARLO DOLCI, is also worth purchasing, and might be obtained at a more moderate cost than those which have been attained.

A LARGE contract will shortly be commenced at Preston, as on Wednesday the tender of Mr. THOMAS A. WALKER, of Great George Street, Westminster, for the construction and completion of the diversion of the Ribble and river entrance for dock, with entrance-gates, timber staging, tidal basin  $4\frac{3}{4}$  acres in extent, locks, lock-gates, dock 40 acres in area, and other works was accepted. The first contract amounts to 439,359*l.*, and the works comprised in it are to be completed before January 1, 1889. A second contract was entered into with Mr. WALKER for deepening the diversion of the river, the amount being 17,000*l.* The town council was authorised to borrow 650,000*l.*

M. CLERMONT-GANNEAU suggests that a museum illustrative of the exploration of Palestine should be formed in London, and in which objects might be arranged according to some system. It should consist, he says, of a vast building in which would be placed together, not only all the local antiquities, all the monuments which could be obtained, but also reproductions in fac-simile, or casts, of monuments that cannot be displaced or that exist in other museums, plans in relief on a large scale, photographs, stereoscopic views, complete and attractive specimens of the animals, flowers, &c., peculiar to the country, costumes, ethnical types, tools, arms, instruments, geological specimens picturesquely arranged, &c. It would be well to join to these an extensive and animated panorama of the Holy City, and dioramic views of the principal localities and of characteristic scenes of popular life in Palestine, in order to add to this scientific combination an irresistible element of attraction and success. A library, containing all the principal publications relating to the Holy Land, and receiving any fresh ones as they appear, should be annexed to it, and put at the disposal of students; rooms reserved for popular or learned lectures. In short, in the centre of London should be created a representation, as faithful, varied, and complete as possible, of Palestine, past and present, which would be as a living commentary on the Bible.

In the International Exhibition of 1851 there was a fine collection of specimens of woods which had been obtained by the industry of Mr. SAUNDERS. From its completeness and interest it was adapted for one of the public museums, but it was not purchased. At the present time there is no collection in Kew or elsewhere in England which will furnish the information respecting timber which is often desired. It appears that the Americans are wiser. The Central Park Museum, New York, contains a collection provided by Mr. MORRIS K.

JESSUP. It comprises every American tree. The pieces obtained are five feet long, and care has been taken to preserve the bark and lichens so that some idea may be formed of the appearance of the tree in the forest. Transverse, longitudinal, and oblique sections are also shown. If the authorities desired, they might be able to do much towards obtaining a similar collection by arranging with the exhibitors of forestry in Edinburgh.

A FEW letters have appeared in the *Times* on the removal of gravel from the foundation of houses. As is usual, the custom which prevails where no architects are employed is supposed to apply to all buildings. One writer relates what was done by the late Sir CHARLES BARRY when rebuilding the College of Surgeons. In digging the foundation the contractors came on a remarkably fine bed of gravel, of so much value that they readily disposed of a large quantity, until Sir CHARLES BARRY on visiting the works at once put a stop to any more being removed, and compelled the contractors to replace what they had taken away with washed Thames gravel and fine powdered lime, well mixed, which concrete made a fine foundation, but cost the contractors far more than they obtained by the sale of the gravel. Clients may be assured that, unless there were arrangements to the contrary, every architect would imitate Sir CHARLES BARRY's example.

THERE are many advantages in having residences near museums for the principal officers. A keeper of a department whose heart is in his work (and no other is fitted for the office) will not be bound by the official five hours a day. He needs often to be at his post before and after the time which answers in Government offices. Sir HENRY COLE, who was not wanting in shrewdness, had official residences erected at South Kensington long before the museum was completed, and the State has been paid in extra work. In the new Natural History Museum no provision has been made for residences, and the reasons for the omission are rather strange. The Government, it appears, arranged that the police should be on duty in the building, and in consequence the advantage of having always one of the principal officers on the spot has been ignored. An ignorant constable is supposed to be an eligible substitute for such a man as Dr. GÜNTHER or Mr. FLOWER. The Trustees have repeatedly declared that "the security of the collections and the government of the museum will not be properly provided for without residences within the precincts, to enable keepers to be at hand at all times, and prepared for all casualties." Afterwards the Trustees declined to hold themselves responsible for the safety of the collections in the absence of an official residence. The Government have considered the subject, but still adhere to the original resolve. As there is plenty of space to build residences, it is difficult for the non-official mind to understand what is the reason for the objection to the residences.

THE power which publicans can exercise in this country has been exemplified in the opposition which has been raised against the completion of a large block of buildings by the Manchester Corporation. Ten years ago a plot of ground containing 5,000 yards was sold to a limited liability company by the Corporation for 284,581*l.*, but only 5 per cent. of the purchase-money was paid. The company proposed to erect an ambitious collection of buildings; but after expending 120,000*l.*, they were forced to stop the works. From their position the unfinished buildings were most unsightly, and impressed strangers with no exalted opinion of the wealth of Manchester. At length the Corporation were compelled to deal with the carcasses of the buildings, and, for the sake of the amenity of the city, to complete the works. This was done with the sanction of the Local Government Board, and under the authority of an Act. It was necessary to carry out the original plan, which included an hotel. It is now objected that the Corporation have no right to set up an hotel in opposition to the ratepayers who are innkeepers. The majority of strangers who visit Manchester will hardly take that view, for the city is below other towns in respect of its hotels. If the plans had been prepared under the inspiration of the Corporation, probably an hotel would not form part of the scheme; but as one was commenced it was necessary to complete it, and the Corporation are simply "making the best of a bad bargain."

## ILLUSTRATIONS.

DESIGNS FOR THE ADMIRALTY AND WAR OFFICES.

WE publish this week two more of the nine designs which formed the second competition. One is the Gothic design by Messrs. GLOVER & SALTER, of Poultry, E.C., and the other is the design by Messrs. MALCOLM STARK, jun., and JAMES LINDSAY, of Glasgow.

## THE ARCHÆOLOGY OF ILKLEY.

A LARGE party, the members of the Yorkshire Archæological and Topographical Association, visited Ilkley on August 27, where the church, Saxon crosses, and other antiquities were examined. Papers were read by the vicar, the Rev. A. C. Downer, and Mr. J. Romilly Allen.

*Ilkley Church.*

The Rev. A. C. Downer, in the course of his paper, said:—In greeting the members of the Yorkshire Archæological and Topographical Association, I may say that it is with sincere pleasure that I welcome them to-day to a spot so rich in historical remains as Ilkley. The field to the north of the churchyard is probably virgin soil so far as discoveries of this kind are concerned, and it would be a work worthy of the Association to undertake, with the owner's permission, to search it. From time to time many antiquities have been found either in the churchyard or in other parts of Ilkley, but many of them in past years were carried off by visitors, who purchased them from workmen and others. It is to be hoped that a more enlightened spirit is now prevalent, and that for the future Ilkley will retain its own treasures. It would be a very satisfactory result of the visit of this Association if a local museum were established in which such remains as may be recovered might be preserved and future discoveries collected. The church and churchyard are particularly rich in these, as it will be known to those present that they occupy the site of the ancient Roman fortress. Coins, pottery, and other articles have been found from time to time in digging graves, and I have a few of these in my possession. The tower was no doubt constructed of the stones of the fortress, as is evidenced by the sculptures still to be seen on the north side of the interior. It was always a puzzle to me when I first came to Ilkley why the arch of the tower was not in the middle, and this was not cleared up until the restoration in 1880, when the plaster was removed from the walls. It then appeared that the original nave wall and clerestory on the south side sprang from the same arch as that on the north side, as can be seen now that the stones are exposed; but at that period, no doubt in consequence of the growing requirements of the place, it had been put back to its present position, and possibly the south aisle added. If this is the case, the church would probably at that time be only one-third of its present size. In connection with the tower there is a niche at the south-east corner of the exterior, above the roof, the object of which I am unable to explain. On the north side of the nave there is a very curious old chapel, which appears to be of earlier date than the rest. The two floriated capitals north and south, at the east end of the nave, are modern, being put in at the restoration in 1861. I believe that eastward from these pillars the church was entirely rebuilt. The church, is, therefore, new and enlarged, and consequently does not call for special remark. The north aisle bears evident tokens of age, and I should say is, near to the door, the oldest portion of the church. There is, however, nothing in it to equal the south doorway, which is a fine specimen of the Norman style. It appears certain that there was at one time a chapel or chantry at the east end of the south aisle, dedicated to St. Nicholas, and, I assume, founded by the Myddelton family. Hopkinson's MSS. in the Leeds Public Library say that William, son of Sir Adam de Myddelton, whose tomb is in the chancel, date 1315, founded a chantry at the Ilkley Church, dedicated to St. Nicholas, and valued at 4*l.* 7*s.* a year. With respect to the antiquities in and about the church, the foremost are the crosses—whether Celtic or Saxon I must leave to the competent hands of Mr. Romilly Allen. I have been to the British Museum about having them housed, but they are considered safer in their present position. Pieces of stone, similarly marked to the crosses, are seen in the window of the south aisle; and another rather different, and now in the vestry, was taken from the clerestory when the windows were made there in 1880. A piece of a different pattern, yet in which the convolutions interlace, found in the Wharfe, has been taken to Myddelton. With regard to the Roman stone in the tower, it is said that there are two—one an altar embossed with a patera, and one the figure which Dr. Whitaker says is representing Hercules strangling the serpents. I regard that as a wild guess. The figure, from its rounded shoulders and general proportions, appears to me rather that of a woman than of the muscular hero; and I venture the suggestion that it represents Verbeia, while the wavy objects she holds in her hands may represent the river over which she presided. In

the north wall of the chancel, with an incised plain cross upon it, is a stone which was either a stone coffin or a very rough grave-stone. There are two piscinæ, one new one marking the site of the old chantry, and the old one removed from that place to the chancel, with what object I cannot say. There are a number of brasses in the church. The most interesting are the set of Heber memorials, and two on the ground near the reading-desk to Richard Hodgson and his son. The ancient oak work was unfortunately reduced in 1861, when much of it passed into the hands of the contractor, and, I fear, is past recovery. There remains an old pew, dated 1633, at the west end, and probably originally erected by a member of the Watkinson family, then an important one in Ilkley; and against the tower is some panelling of the same period, with pretty leaf-work and in good preservation. The register commences with the year 1597, and is in good preservation. A small portion of it has been preserved for generations in a private family, but it may be hoped that it will ultimately be restored to its original position. There are also books of the Dole Churches and old relics of churchwardens' accounts, appointments of sextons, dogwhippers, &c.

*The Ilkley Crosses.*

Mr. J. Romilly Allen read a paper on the Ilkley crosses. He said:—The history of the Ilkley crosses takes us back to the dawn of Christianity in the north of England, when Yorkshire formed a portion of the kingdom of Northumbria, which extended from the Humber to the Forth. Shortly after the departure of the Roman legions from Britain, the English invasion burst in all its fury upon our shores, and separated the Church of Ireland from the rest of European Christendom by an intrusive wedge of heathenism. No sooner, however, had the English settled down in their new home than this wedge of heathenism, which had been driven by sheer brute force into the midst of a Christian community, experienced the moral strength of the Gospel of Christ pressing on it from both sides. Thus, whilst Augustine brought the Christianity of Rome to the shores of Kent, Columba carried the Celtic Christianity of Ireland to Iona, whence Aidan went forth as a missionary to Lindisfarne, where a centre was established for the conversion of Northumbria. The moral effect of Aidan's teaching was to substitute civilisation for barbarism. One of the material results which accompanied it is now before us in the beautifully sculptured crosses, which, after being associated with the changing fortunes of Ilkley for a thousand years, still bear witness to the triumph of the religion of Christ over that of Woden and Thor. The earliest Christian memorials in Great Britain are rude pillar stones, untouched by the chisel, except where an inscription is cut in debased Roman capitals on cryptic oghams, the language being either Latin or Celtic. They belong to the transition period between Paganism and Christianity, and are found only within the purely Celtic area of Wales, Scotland, Ireland, and the West of England. Some of these pillar stones are possibly as old as the fourth or fifth centuries, although the dates of none of them have been ascertained from historical evidence. Next in age to the pillar stones come the elaborately carved crosses, such as those at Ilkley, ranging as regards date between the seventh and eleventh centuries. The characteristic features of these crosses are as follows:—(1) The cross is either hewn out of one block of stone, or the head is formed out of a separate piece and mortised into the shaft, the whole being firmly fixed in a solid stone base or socket. (2) The shaft is of rectangular section, tapering towards the top, and the head has four circular hollows at the angles, formed by the intersection of the limbs, and the limbs are often encircled by a ring. (3) The ornament is usually arranged in panels, separated from each other by horizontal bands, and a bead or cable moulding runs up the angles of the shaft. (4) The ornament is typically Celtic, and similar to that found in the MSS., and on metal-work of the same period in Ireland, consisting of spirals with expanded ends, key patterns arranged diagonally, interlaced work, dragonesque shapes, scrolls of foliage, and scenes from Scripture. (5) The inscriptions, when they occur, are generally to the effect that "A erected this cross to the memory of B. Pray for his soul." The characters are either Saxon uncials, Irish minuscules, or Scandinavian runes, and the language old English or Latin. There is considerable difference of opinion as to why those crosses were erected. Some such as those formerly existing at Ripon marked the boundaries of sanctuary, others are, no doubt, memorial, and I think it quite possible that many were set up by the early missionaries to commemorate the conversion of a district, and to mark the site of the church, which was to be built when the necessary funds were collected. The dates of most of these crosses can only be arrived at approximately, but it is known that the characteristically Celtic patterns with which they are adorned originated in MSS. in the seventh century, and attained the highest perfection in sculptured stonework in the beginning of the ninth century, and in metal-work in the tenth and eleventh centuries, finally becoming extinct after the Norman Conquest. The Lindisfarne Gospels, the glory of the Cottonian Library in the British Museum, exhibit the most perfect specimen of Hiberno-Saxon illumination we possess, and the date is known to be between 698 and 721, as they contain a memorandum showing that they were executed by

the orders of Bishop Eadfrith, the successor to St. Cuthbert. The magnificent Celtic cross at Clonmacnois, which marks the culminating point of Celtic art in stonework, bears an inscription showing that it was erected by the Abbot Colman, and its date is fixed by historic evidence as being 914. The processional cross of Cong, which is in the best style of Celtic metal-work, bears an inscription fixing its date in the year 1123. Having now discussed the subject from a general point of view, I propose to call attention to the peculiarly-interesting features of the Ilkley crosses. The first historical notice we have of these monuments is in Camden's "Britannia," where they are briefly referred to as "pillars of Roman work." All that now remains of what must once have been three very beautiful crosses are the complete shaft of the central one and the mutilated shafts of those on each side. The mortice holes for fixing on the heads of two of them still exist, and in the grounds of Myddelton Hall is a portion of one of the heads. A few years ago the base of the central cross was surrounded by three circular steps, which concealed the lower portion, as can be traced by the weathering of the stone. One of the other shafts was used for a long time as a gate-post in the churchyard wall, and consequently shockingly defaced. All three shafts are now securely fixed in a new stone base, and it is to be hoped that there is no further chance of injury. The central shaft is the most important, both on account of its great size and the special interest of the sculptures. On one side are the symbols of the four evangelists, and on the other the Lord holding a pastoral staff. From the third to the thirteenth centuries Christ surrounded by the symbols of the four evangelists is one of the most common subjects which occurs upon Christian monuments, but the method of representation changed considerably as time went on. In the catacombs at Rome in the early centuries Christ is symbolised by the cross and the four evangelists, by four books or scrolls at each of the corners, or, again, Christ is represented as the Agnus Dei, standing upon the mountain of Paradise, from the base of which issue four rivers, which are the four evangelists. As early as the sixth century we find the evangelists symbolised by the four beasts described in the Apocalypse, St. Matthew having the face of a man, St. Mark that of a lion, St. Luke that of a bull, and St. John that of an eagle, and they carry either books or scrolls in their hands. Generally the bodies are those of winged beasts, but on the Ilkley cross the bodies are human. This curious deviation from the usual method of representation occurs only in a few rare instances, as on a Saxon slab at Wirkworth Church, in Derbyshire, and in one or two MSS. Above the Norman doorway of Adel Church is a good example of Christ as the Agnus Dei surrounded by the four symbolical beasts. In connection with the present subject it may be mentioned that the cross of Clonmacnois, in Ireland, which is sculptured with scenes from the life of our Lord, is referred to in Irish annals, under the date 1060, as the "Cross na Screaptra," or cross of the Scriptures, and the same name might fairly be given to the cross of Ilkley. Three of the panels of the central shaft are sculptured with grotesque animals, arranged systematically in pairs facing each other, or shown singly with one paw upraised and the tails interlaced. The two sides are ornamented with scrolls of graceful foliage, such as occurs on many of the stones of this period within the ancient Northumbrian area, but not in the Celtic MSS., or on stones in Scotland north of the Forth, or in Wales or Ireland. The carving on the two smaller shafts is of a similar character with that on the centre one, consisting of conventional foliage and animals, together with interlaced work, and in one case a human figure holding a book. The meaning of the monstrous animal forms which are found so frequently upon the stones of this class has not yet been satisfactorily explained, but perhaps a study of the various manuscripts of the Middle Ages may eventually throw more light on the matter. In addition to the shafts of the three crosses in the churchyard, there are fragments of at least two others preserved within the church. In conclusion, I hope I have succeeded in showing that the Ilkley crosses are historical landmarks of the very highest importance, both as bearing witness to the establishment of Christianity upon this hallowed spot one thousand years ago, and testifying to the comparatively advanced stage which art culture had reached in Northumbria at that remote period.

#### *The Rock Sculptures of Ilkley.*

Mr. Allen then read a paper on "The Rock Sculptures of Ilkley." He said:—"Perhaps one of the greatest charms of the scenery of this part of Yorkshire is the way in which, by climbing a few hundred feet up a hillside, one passes suddenly out of the fertile valley, with its broad meadows, to find oneself in the midst of wild moors covered with purple heather and grey weather-stained rocks. An equally rapid change takes place with regard to the archaeological surroundings. Roman camp and altar, Christian cross and church are left behind, and we find ourselves face to face with the burial mounds and sacred rocks of the primæval men. It is with the sculptures on the latter that we have now to deal. Upon the south side of the valley of the Wharfe, behind the town of Ilkley, is a line of the gritstone crags, extending for about four miles from the Cow and Calf towards Addingham, and rising gradually from 800 feet to 1,000 feet above

the level of the sea. These crags form the line of demarcation between the fertile valley of the Wharfe and Rumbolds Moor and the prehistoric sculptures which form the subject of the present paper. The most important groups are situated near the Panorama Rock and near the Cow and Calf. The sculptures belong to the class known as the cup-and-ring markings, on account of their shape. The simplest form is a cup-shaped depression, varying from 1 inch to 3 inches in diameter. This is often surmounted by one or more concentric grooves about an inch wide and the same distance apart. Sometimes there is a straight radial groove, and, lastly, the ends of these radial grooves are in many cases connected by an elaborate system of channels. Cup markings were observed at Old Berwick, in Northumberland, as far back as 1825. I believe that the late Dr. Call was the first to notice the rock sculptures at Ilkley, and it is entirely to him that I owe my knowledge of their existence, although it is to my friend Mr. Fred Fison I am indebted for having been shown several new examples. There are a large number of sculptured rocks on Rumbolds Moor already known, and no doubt there are many more yet to be discovered. Most of the sculptures are of the usual type, but there are others that call for comment. Near the Panorama Rock are three large masses of ironstone close together, and averaging ten to twelve feet across each way, the horizontal surfaces of which are covered with cups and rings, and two of these stones have also a peculiar arrangement of grooves somewhat resembling a ladder in form. This pattern occurs in only one other stone at Ilkley, which was discovered by Mr. Frederick Fison in 1878. At Woodhouse Crag is a mass of gritstone bearing a pattern which also occurs in Sweden, namely, that of the Swastika or Buddhist cross. It would seem, therefore, that there is thus established a link between the sculptures of Sweden and Ilkley. Besides the variations in the carvings upon the stones on Rumbolds Moor, it must be noticed that many of the rocks upon which the sculptures occur are very remarkable in shape, and often have curious names. The stones on Addingham High Moor are striking, both as regards form and position. Having thus glanced briefly at some of the most characteristic features of the Ilkley rock sculptures, we lastly come to the question of their origin and meaning. There is no satisfactory theory on the subject, though the mystery may in time be solved. The Druidic theory is played out, and our knowledge of the Druids consists only of a few passages from Latin authors, which, collected together, would go on to a sheet of ordinary note paper; and there is nothing absolutely to connect them with the megalithic remains of the pre-historic period. In endeavouring to form a theory as to the origin of cup and ring, the first thing that strikes one is the monotony with which the same features are repeated over and over again, and the utter absence of any arrangement or design of any kind in the position of the figures relative to each other. I think from these two peculiarities we may deduce the following:—(1) That the cups and rings were either sacred symbols, or that the cups and grooves were adapted by their shape to some ceremonial use; (2) that the irregularity in the arrangement can only be accounted for by the fact that they were executed by different persons at the same time, or by the same person at different times. There is a good deal to be learned from the geographical distribution of rocks with cup markings. There are in England and Wales 102, in Scotland 204, in Ireland 42, France 21, Switzerland 32, and Scandinavia 42. In all these cases the sculptures are of exactly the same type except in Sweden, where the drawings are associated with rude drawings of men, animals, &c. It is evident that the race who carved these rocks must have spread or passed over the greater part of Europe, for the most important fact connected with the cup and ring markings is their being found in a large number of instances in connection with sepulchral remains, such as stone circles, cist and urn covers. We are thus enabled to say with certainty that some at least of the cup-marked stones are of the bronze age, on account of the sepulchral remains found in connection with them. Cup marks are applied to superstitious uses still in many places. Cup marks have been found in India on rocks and sepulchral monuments, and it may eventually turn out that they are of Eastern origin, and that their meaning and use is still understood in that country.

#### THE SEVERN TUNNEL RAILWAY.\*

IN former days before railways existed, one of the coach roads between England and South Wales crossed the Severn near the place where a railway tunnel is now being made. In those times travellers left their coaches on reaching the Severn at New Passage on one side and Portskewet on the other, and crossed the river or estuary, which is there about 2½ miles wide, in open boats.

Later on, lofty wooden piers were made on the banks of the Severn at the two places just named; on to these the trains now run, and passengers there leave them, and are taken across the river by steam ferry-boats. The inconvenience of this journey is

\* From a paper by Mr. J. Clarke Hawshaw, read before the British Association at Montreal.

increased by the great rise of tide, amounting at springs to over 40 feet.

To do away with this break in the railway communication between the two parts of the country, plans were submitted to Parliament, one for the construction of a bridge, and the other of a tunnel.

In the year 1872 Parliament sanctioned the construction of a tunnel, and the work was begun in March 1873 by the Great Western Railway Company. Shafts were sunk, and from them driftways were driven on the line of the tunnel. In this preliminary work no great difficulty was encountered, and the driftway under the river was nearly completed, only 130 yards remaining to be driven in order to effect a junction, when a large spring burst into the driftway, driven landwards from Sudbrook, and drowned the works under the river.

This happened on October 16, 1879. Sir John Hawkshaw, who had previously acted as consulting engineer, was appointed engineer-in-chief in conjunction with the engineer Mr. Richardson, and a contract was made with Mr. T. A. Walker for the completion of the works. Considerable progress has been made with them during the last 4½ years, and the tunnel is now rapidly approaching completion.

The line selected for the tunnel is about half a mile south of the steam ferry between New Passage and Portskewet. The Severn is there about 2½ miles wide, and is a tidal estuary rather than a river. Owing to the great rise of tide the current is very rapid, reaching 10 to 11 knots in certain states of the tide. The bed, which is laid bare over two-thirds of the width of the estuary at low water, consists throughout of rock or shale. There are three depressions in it. The most considerable, called the "shoots," is half a mile from the Welsh shore, and has a width of 550 yards, and a depth of 60 feet at low water and 96 feet to 100 feet at high water.

A section made on the line of the tunnel would disclose below recent surface deposits a series of trias marls and sandstones lying in nearly horizontal strata on highly-inclined beds of coal measure, shales, and sandstones.

The tunnel itself passes for the greater part of its length through trias mostly in the form of nearly horizontal beds of marl, much jointed, the joints often open, and yielding in many places a great quantity of water; near the eastern face the upper part of the tunnel for a short distance is in the gravel overlying the marl, then wholly in marl, passing before the coal measures are reached into a compact fine grained sandstone. The passage from trias marls to the coal measures, which takes place at a distance of about a mile from the sea wall is abrupt owing to faulting. For the remaining distance under the river the rocks traversed consist of coal measure shales and sandstones, under the shoots; where the cover above the tunnel is only 45 feet the sandstone is strong Pennant, much broken and jointed, though sometimes in massive beds. Much water flowed from the open joints in this sandstone in many places.

The tunnel continues in the coal measures for a distance of about a quarter of a mile after reaching the Welsh shore, where they are found in the form of red shales and sandstones, generally very free from water. From these shales the tunnel passes gradually into the overlying conglomerate at the base of the trias. This was the most troublesome formation to tunnel through. At the middle shaft it is 26 feet thick, full of open fissures discharging a great volume of water. From the conglomerate the tunnel again passes into the trias marls, and continues in them for the remaining distance to the western face.

The total length of the tunnel when finished will be 7,664 yards (about 4½ miles); the length of the tunnel sanctioned by Parliament in 1872 was 4½ miles, but in 1883 an application which was granted was made to reduce the length by 13 chains, by substituting that length of open cutting for tunnel at the Welsh end. This was done with a view to obtain material for making embankments for sidings at Rogiett Station, where the Tunnel Railway joins the South Wales line.

Another important alteration was made in the design after the works had made considerable progress. When Sir John Hawkshaw was appointed engineer in 1879, he recommended that the line of the tunnel should be lowered 15 feet under the Severn in order to obtain more cover. The lowest part of the line was placed under the shoots, the deepest part of the estuary. The minimum cover then was 30 feet, which has been increased by lowering the level 15 feet to 45 feet. Under the shoots the line will be on the level for 12 chains. From this level piece the line rises with a gradient of 1 in 100 towards the English end and 1 in 90 towards the Welsh end. Originally the gradients were 1 in 100 each way. The gradient on the Welsh side was made steeper in order to avoid deepening the cutting at the Welsh end, and so save excavation. As the heavier loads are mostly from Wales to England, this alteration of gradient will not be much felt in working the line; and as very little of the Welsh incline lies under the river, there is only a short length of tunnel under the Severn which will not be lowered the full 15 feet. The English incline has been lowered 15 feet throughout. This alteration added about 430,000 cubic yards of excavation to the cutting at the English end.

Prior to this alteration a drainage driftway had been driven from the pumping shaft at Sudbrook to the lowest part of the tunnel heading under the shoots. A second heading has now been driven at a lower level to drain the tunnel as it is being constructed. This heading is circular and 5 feet in diameter inside the brickwork (13½ inches thick), with which it is lined throughout. The tunnel is for a double line of way, lined throughout with brickwork. The top is a semicircle of 13 feet radius, with curved side walls and invert.

The transverse section of the tunnel shows the lining of brickwork to be 2 feet 3 inches thick. This was the contract section; but under the shoots under the Salmon Pool, and in other parts where the nature of the ground rendered it advisable, the thickness was increased to 3 feet in the arch and side walls. In a few places the invert was reduced to 1 foot 10 inches and 1 foot 6 inches in thickness. The bricks used are all vitrified. They are frequently tested with an hydraulic machine kept on the works for the purpose, and have borne from 25 tons to 70 tons without cracking, and as much as 77 tons before they were crushed. Some came from Staffordshire, some from the neighbourhood of Bristol, and from Cattybrook in Gloucestershire, near where the tunnel line joins the line from Bristol. They are all made from coal measure shales. As these shales are met with in the works, the contractor has erected crushing mills, drying sheds, and kilns, and makes 150,000 to 170,000 a week for use in the works.

The greatest amount of brickwork that has been done in one week is 2,000 cubic yards, requiring two-thirds of a million bricks. The brickwork is all set in mortar made of one part of Portland cement and two parts of sand. When much water was met with, it was led to pipes which are built into the brickwork. Some of these have been plugged up, but through many of these the water is still flowing. The largest pipe required for this purpose is 6 inches in diameter, from which a stream of water of the full section issued under considerable pressure at the time of high tides. Pipes could be only used when the water to be dealt with came in a definite stream from a fissure. In many cases in marl the water issued all over the section of the marl exposed in the excavation. It then became necessary to cover the whole surface with roofing felt in two thicknesses before any brickwork could be set. The time occupied in doing this, and in making other arrangements for keeping the water off the brickwork, more than trebled the total time which would have been required to finish a length of brickwork in a dry section of the tunnel.

The only really dry parts of the work were those in the fine-grained trias sandstone under the river in some of the coal measure shales, and in the higher beds of the trias marl and sandstone near the west end of the tunnel.

Some of the excavation for a short distance near the east end of the tunnel was in gravel. This owing to its loose and open nature required very heavy timbering. Almost the whole of the remainder, the exception being a short length of the softer coal measure shales, was in material so hard as to require blasting. Holes were drilled partly by hand and partly by machines worked by compressed air. When the Great Western Railway Company were carrying on the works themselves they used a machine made at their works at Swindon, and as a number of these were handed over to Mr. Walker when he took the contract, a great part of the work was done with them. They are very rapid in doing their work, but require constant repair. Several other drills were tried, the Darlington being most in favour owing to its scarcely ever wanting repairs. Several sorts of explosives were used, but torrite principally; its fumes being found less noxious than those of dynamite. As much as 6,000 lbs. have been sometimes used in one week. The greatest amount of excavation in tunnelling done in any one week was 6,000 cubic yards.

The driftways as originally driven were bottom driftways, but owing to the tunnel being made at a lower level than was originally intended, and the gradient altered, they became neither bottom nor top driftways in most places, and it was necessary to drive a new bottom driftway almost throughout the whole length of the work.

From the driftways breakups were made at intervals of about two to five chains. Some timbering was necessary in almost every length. In the gravel and shales this was of the heaviest description. Some of the Pennant, the dolomitic conglomerate, and some of the trias sandstone, stood with little or none.

Four steam-navvies are now at work in the cutting at the English end, which contained 790,000 cubic yards of excavation. This cutting is almost wholly in alluvium gravel and sand. The cutting at the Welsh end is partly in alluvium and partly in trias sandstone; it is now nearly completed.

Embankments are made along the sides of the cuttings throughout their lengths to protect the tunnel in the event of the low lands through which they pass being flooded.

The total quantity of water now being pumped is about 19,000 gallons per minute. Four beat valves of gun-metal are used in all the large pumps, and they have been found to work very satisfactorily.

On the 4½ miles of tunnel there are shafts at seven points, viz., at each face and at five intermediate points. The greatest dis-

tance between any two shafts is 2 miles 25 chains between the shafts at the sea-wall and Sudbrook, which are separated by the Severn. The other shafts are from 25 to 40 chains apart at sea-wall, and also at middle shaft; there is in addition to the winding-shaft a pumping-shaft, and at Sudbrook there are now three pumping-shafts and one winding-shaft; one of these three pumping-shafts was till lately used as a winding-shaft. All the pumping-shafts except the last-mentioned are off the line of the tunnel, and connected with the works by culverts, which can be closed by sluices, so that in the event of a pump breaking down, the shaft can be kept dry by closing the sluice until the repairs are done.

The shafts were all lined with brickwork set in Portland cement mortar, excepting that at the west face, which was not lined, and one pumping-shaft at Sudbrook intended to be a permanent pumping-shaft, which is lined with cast-iron tubing.

As has been already stated, the driftways originally driven were bottom driftways, but owing to the alteration in the level of the tunnel they ceased to be so before the enlargement, for the permanent work was begun under the Salmon Pool, and, under the shoots the arch of the tunnel was turned without side walls from the existing driftway. It was, however, soon found necessary to drive a new one at invert level for drainage purposes throughout nearly the whole length of the work.

The driftways were from 7 feet to 9 feet square. Timber was not required in them in the more compact beds of marl and sandstone and in the conglomerate.

So long as the driftways from the different shafts were in progress ventilation was effected by the compressed air which was used for the rock-drills, supplemented in one or two cases by pipes of larger diameter, through which air was forced by blowers. After the driftways had been joined under the river a fan was provided at Sudbrook, 18 feet in diameter by 7 feet wide, worked by an engine of ten horse power. This fan effectually ventilated the workings under the river. Electric light is largely used both above ground and in those parts of the workings underground where the brickwork is completed. Lights of 2,000-candle power are suspended at intervals of about ten chains in the finished parts of the tunnel. Much vitiation of the air is prevented by the use of these lights.

### PRE-HISTORIC ARCHÆOLOGY IN AMERICA.

AN address was delivered by Dr. E. B. Tylor, as president of the section of Anthropology at the meeting of the British Association in Montreal, in which he referred to the relations between the eastern and western parts of the globe. The following is an extract:—Of late no great progress has been made toward fixing a scale of calculation of the human period, but the arguments as to time required for alterations in valley-levels, changes of fauna, evolution of races, languages, and culture, seem to converge more conclusively than ever toward a human period, short indeed as a fraction of geological time, but long as compared with historical or chronological time. While, however, it is felt that length of time need not debar the anthropologist from hypotheses of development and migration, there is more caution as to assumptions of millions of years where no arithmetical basis exists, and less tendency to treat everything pre-historic as necessarily of extreme antiquity, such as, for instance, the Swiss lake-dwellings and the Central American temples. There are certain problems of American anthropology which are not the less interesting for involving no considerations of high antiquity; indeed they have the advantage of being within the check of history, though not themselves belonging to it. Humboldt's argument as to traces of Asiatic influence in Mexico is one of these. The four ages in the Aztec picture-writings, ending with catastrophes of the four elements, earth, fire, air, water, compared by him with the same scheme among the Banyans of Surat, is a strong piece of evidence, which would become yet stronger if the Hindoo book could be found from which the account is declared to have been taken. Not less cogent is his comparison of the zodiacs or calendar-cycles of Mexico and Central America with those of Eastern Asia, such as that by which the Japanese reckon the sixty-year cycle by combining the elements seriatim with the twelve animals, mouse, bull, tiger, hare, &c.; the present year is, I suppose, the second water-ape year, and the time of day is the goat-hour. Humboldt's case may be reinforced by the consideration of the magical employment of these zodiacs in the Old and New World. The description of a Mexican astrologer, sent for to make the arrangements for a marriage by comparing the zodiac animals of the birthdays of bride and bridegroom, might have been written almost exactly of the modern Kalmuks; and in fact it seems connected in origin with similar rules in our own books of astrology. Magic is of great value in thus tracing communication, direct or indirect, between distant nations. The power of lasting and travelling which it possesses may be instanced by the rock-pictures from the sacred Roches Percées of Manitoba, sketched by Dr. Dawson, and published in his father's volume on "Fossil Man," with the proper caution that the pictures, or some of them, may be modern. Besides the rude pictures of deer and

Indians and their huts, one sees with surprise a pentagram more neatly drawn than that defective one which let Mephistopheles pass Faust's threshold, though it kept the demon in when he had got there. Whether the Indians of Manitoba learnt the magic figure from the white man, or whether the white man did it himself in jest, it proves a line of intercourse sketching back 2,500 years to the time when it was first drawn as a geometrical diagram of the school of Pythagoras. To return to Humboldt's argument, if there was communication from Asia to Mexico before the Spanish Conquest, it ought to have brought other things, and no things travel more easily than games. I noticed some years ago that the Aztecs are described by the old Spanish writers as playing a game called patolli, where they moved stones on the squares of a cross-shaped mat, according to the throws of beans marked on one side. The description minutely corresponds with the Hindoo game of pachisi, played in like manner with cowries instead of beans; this game, which is an early variety of backgammon, is well-known in Asia, whence it seems to have found its way into America. From Mexico it passed into Sonora and Zacatecas, much broken down but retaining its name, and it may be traced still further into the game of plumstones among the Iroquois and other tribes. Now, if the probability be granted that these various American notions come from Asia, their importation would not have to do with any remotely ancient connection between the two continents. The Hindoo element-catastrophes, the East Asiatic zodiac-calendars, the game of backgammon, seem none of them extremely old, and it may not be a thousand years since they reached America. These are cases in which we may reasonably suppose communication by seafarers, perhaps even in some of those junks which are brought across so often by the ocean-current and wrecked on the Californian coast. In connection with ideas borrowed from Asia there arises the question, How did the Mexicans and Peruvians become possessed of bronze? Seeing how imperfectly it had established itself, not even dispossessing the stone implements, I have long believed it to be an Asiatic importation of no great antiquity, and it is with great satisfaction that I find such an authority on pre-historic archæology as Professor Worsaae comparing the bronze implements in China and Japan with those of Mexico and Peru, and declaring emphatically his opinion that bronze was a modern novelty introduced into America. While these items of Asiatic culture in America are so localised as to agree best with the hypothesis of communication far south across the Pacific, there are others which agree best with the routes far north. A remarkable piece of evidence pointed out by General Pitt-Rivers is the geographical distribution of the Tartar or composite bow, which in construction is unlike the long bow, being made of several pieces spliced together, and which is bent backwards to string it. This distinctly Asiatic form may be followed across the region of Behring's Straits into America among the Esquimaux and northern Indians, so that it can hardly be doubted that its coming into America was by a northern line of migration. This important movement in culture may have taken place in remotely ancient times. A brief account may now be given of the present state of information as to movements of civilisation within the double continent of America. Conspicuous among these is what may be called the northward drift of civilisation, which comes well into view in the evidence of botanists as to cultivated plants. Maize, though allied to, and probably genetically connected with, an Old World graminaceous family, is distinctly American, and is believed by De Candolle to have been brought into cultivation in Peru, whence it was carried from tribe to tribe up into the North. To see how closely the two continents are connected in civilisation, one need only look at the distribution on both of maize, tobacco, and cacao. It is admitted as probable that from the Mexican and Central American region agriculture travelled northward, and became established among the native tribes. This direction may be clearly traced in a sketch of their agriculture, such as is given in Mr. Lucien Carr's paper on the "Mounds of the Mississippi Valley." The same staple cultivation passed on from place to place—maize, haricots, pumpkins for food, and tobacco for luxury. Agriculture among the Indians of the great lakes is plainly seen to have been an imported craft by the way in which it had spread to some tribes but not to others. The distribution of the potters' art is similarly partial, some tribes making good earthen vessels, while others still boiled meat in its own skin with hot stones; so that it may well be supposed that the arts of growing corn and making the earthen pot to boil the hominy came together from the more civilised nations of the south. With this northward drift of civilisation other facts harmonise. The researches of Buschmann, published by the Berlin Academy, show how Aztec words have become embedded in the languages of Sonora, New Mexico, and up the western side of the continent, which could not have spread there without Mexican intercourse extending far north-west. This indeed has left many traces still discernible in the industrial and decorative arts of the Pueblo Indians. Along the courses of this northward drift of culture remain two remarkable series of structures probably connected with it. The Casas Grandes, the fortified communal barracks (if I may so call them) which provided house-room for hundreds of families, excited the astonishment of the early Spanish explorers, but are only beginning to be thoroughly

described now that such districts as the Taos Valley have come within reach by the railroads across to the Pacific. The accounts of these village forts and their inhabitants, drawn up by Major J. W. Powell, of the Bureau of Ethnology, and Mr. Putman, of the Peabody Museum, disclose the old communistic society surviving in modern times, in instructive comment on the philosophers who are seeking to return to it. It would be premature in the present state of information to decide whether Mr. J. L. Morgan, in his work on the "Houses and House Life of the American Aborigines," has realised the conditions of the problem. It is plausible to suppose with him a connection between the communal dwellings of the American Indians, such as the Iroquois long-house with its many family hearths, with the more solid buildings inhabited on a similar social principle by tribes such as the Zuñis of New Mexico. Morgan was so much a man of genius that his speculations, even when at variance with the general view of the facts, are always suggestive. This is the case with his attempt to account for the organisation of the Aztec state as a highly-developed Indian tribal community, and even to explain the many-roomed stone palaces, as they are called, of Central America, as being huge communal dwellings like those of the Pueblo Indians. I will not go further into the subject here, hoping that it may be debated in the section by those far better acquainted with the evidence. I need not, for the same reason, do much more than mention the mound builders, nor enter largely on the literature which has grown up about them since the publication of the works of Squier and Davis. Now that the idea of their being a separate race of high antiquity has died out, and their earthworks with the implements and ornaments found among them are brought into comparison with those of other tribes of the country, they have settled into representatives of one of the most notable stages of the northward drift of culture among the indigenes of America.

### ST. HELEN'S TOWN HALL.

AT the meeting of the St. Helen's Town Council on Wednesday the Parliamentary Committee, to whom the question of the decoration and renovation of the Town Hall buildings had been referred, recommended the Council to invite tenders for carrying out the following works:—Cleaning, painting, and decorating the whole of the interior of the building; the facing with a dado of tiles of the whole of the corridors and staircases; facing with marble the walls of the assembly-room as high as the cornice, and screens for platform; lining the whole of the walls of the council-chamber with oak or walnut panelling, including furniture, with clock over fireplace, panelling with sounding board behind the mayor's chair, and decorated frieze; rearrangement of surveyor's offices, embracing an extension of the drawing office, provision of plan-room, and consequent alteration of lavatories; alterations to enable the use of the room over the water engineer's office as a committee-room; wind screen or porch for Hardshaw Street entrance; repairs to roof and strengthening of gallery of assembly-room; heating and ventilation of the whole of the building. Estimated cost (not including repairs of roof and strengthening of gallery, for which the architect stated it was not possible to estimate), 6,539/.

### NOTES ON NOVELTIES.

**The "Chelsea" Improved Mortise and other Locks.**—The improvements made in iron safes since the first half of the present century passed away caused considerable rivalry amongst the better class of lockmakers, and those whose recollections carry them over the period named, may remember the challenges that have from time to time been issued by rival makers of sums of money to be awarded if anyone could pick their locks, and the names of Chubb, Cotterill, Hobbs, Tann, &c., are amongst those who have claimed to have invented these mechanical appliances that would baffle the most ingenious burglar or mechanic. But the staple lock trade of the country had undergone very little change during this time, and it was not until America some eight years since commenced to send her locks into the United Kingdom that the lockmakers of Staffordshire found it necessary to rouse themselves from the state of lethargy into which they had fallen, that is to say, in being content to make the same kind of goods year after year without any attempt at improvement. The first shipments of American locks here were certainly cheaper than similar articles of home make were then being sold at, and there were points about them worth attention. Then we were for a time deluged with the commoner sorts which, made principally of cast iron though of considerable malleability, were eagerly bought on account of their extreme low price by the ironmongers and speculative builders. Immense excitement was caused for a time in the hardware world, and trade journals were week by week teeming with prognostications as to the eventual collapse of the lock industry in this country. The Paris exhibition of 1878 tended to increase this feeling, for there American locks were in great force

and what was most disappointing to Englishmen interested in the question was, that our own makers were scarcely represented at all save by a few of the important "safe" makers, which gave a colourable sequence to the feeling before named. But our "cousins" were not allowed to revel long in the luxury they fancied they had attained. For a short time matters certainly looked adverse to English interests, but the low-priced locks were proved to be little else than rubbish, while as regards the better-class ones our manufacturers were enabled to produce locks with the best points contained in the transatlantic productions, but more suitable to English notions at a lower cost. Amongst the changes brought about by this *coup* has been a desire to reduce the size of the mortise lock, and in some instances of the keys, and to nickel plate the latter. Travellers on the Continent must often have been struck by the large size of the door locks, the majority of which are "rim," and of the keys also. The large key gives no additional security, and it has been clearly shown that the size of an ordinary lock can be reduced and prove as effectual as the old patterns. The "Chelsea" patent locks introduced by Messrs. Broughton & Co., 169 Queen Victoria Street, E.C., of which we give an illustration of the "Mortise," is a step in the direction we have mentioned;

and they are also made on the same lines in "Mortise Dead," "Mortise Latch," and "Mortise Night Latch." It will be observed that the solid square case is here dispensed with, and only two small ones, one 5½ inches deep and another 4 inches deep (which the makers advise to be made with a one-inch Jennings's screw-pointed centre-bit), with a third in the centre ½-inch deep, and it is claimed that a mortise lock may be fixed in five minutes, including the cutting of the holes. By this means the injury to the door is materially reduced, and knocking about with chisel and mallet is dispensed with. One screw only is required to secure the lock in its position, and this is so arranged that, by unscrewing it, the lock is simultaneously withdrawn, rendering its removal an easy matter for repairs, repainting door, &c. A much longer screw can also be used for securing the roses, as they do not come in contact with the case of the lock, but go into the solid woodwork above and below it. The latch, or "catch" bolt, is also reversible, and can be altered to right or left hand without opening the case. The bearings of the "follower" are extra wide, which insures longer wear, and the follower is constructed so that its action on the bolt shall be smooth both ways. The materials of which these locks are made are of the best description, the cases being of rolled steel with brass front plates, and the followers of gun-metal or phosphor bronze, and the parts work with the greatest ease and regularity. Very specific instructions are sent out with each lock for fixing, so that the most commonplace workman can understand them, and for a first-class lock the prices are very reasonable. We think that their advantages will be fully recognised by the profession, and for thin doors especially this will be brought out.

**Patent Gas Tubing.**—An elastic rubber tubing perfectly gas-tight and free from smell has been urgently needed for many years—in fact the impossibility of making satisfactory gas connections for gas apparatus which requires to be movable has rendered the use of gas as a fuel in many cases a most objectionable nuisance. The tubing recently patented is made of two layers of rubber, with pure soft tinfoil vulcanised between. It is perfectly and permanently gas-tight under any pressure, and free from the slightest trace of smell after long continued use, whilst it retains the flexibility and elasticity of an ordinary rubber tube. The braided or cloth-covered tube, which has been made with the intention of filling this want, has never come into general use owing to the very small quantity of gas it passes, rendering it almost useless except for small lighting burners; and also that special brass connections and screws have to be fitted to every burner, and to both ends of every length of tube. Both these serious faults are entirely done away with. This tube is the result of many years' experiments. Irrespective of the well-known fact that extremely thin layers of rolled or beaten metal are perfectly gas-tight, the tube has been in practical use for some time, and has been thoroughly tested under continuous and heavy pressures of gas. The inventor and manufacturer is Mr. Thos. Fletcher, F.C.S., of Warrington.

**Wood-Block Flooring.**—The subject of wood-block flooring is now receiving a considerable amount of attention, and, as most

of our readers will be aware, was discussed at some length at the Conference of Architects held a few weeks ago at the Health Exhibition. The general opinion expressed at this meeting, and in which we entirely concur was, that wood-block floors are in every respect to be preferred to the ordinary boarded floors, and no doubt the latter will in time be superseded to a great extent by the more solid and durable floor, as even now it is extensively employed. We believe that this flooring would have been more generally used than has hitherto been the case, but for one drawback—the liability of the blocks to become loose soon after being laid. This objection has not now, however, any standing, as for some time past this flooring has been laid—notably by Messrs. Geary & Walker, of Manchester—on a principle which is positively preventative of “loose blocks,” and is, moreover, essentially the system advocated by Mr. E. C. Robins, Mr. A. Waterhouse, and others who have had no inconsiderable experience of this class of flooring. In these floors it is very inadvisable for architects to permit the use of long and narrow blocks, as they are at all times liable to warp and become loose. Mr. Robins advises the use of 6-inch and 3-inch blocks,  $1\frac{1}{2}$  inch or 2 inches in thickness, and we certainly think that 9 inches, or, at the outside, 12 inches in length, should be the limit. The many ways in which this flooring can be treated renders it most suitable for almost every class of building, and there is little doubt that when its unmistakable advantages become more widely known, it will be generally adopted.

#### Tests of American Bricks.

Office Supervising Engineer and Architect,  
New Pension Building,  
1316 N Street N.W., Washington, D.C.

SIR,—Referring to your note in issue of August 9 upon the tests of bricks offered for the new United States Pension Building in this city, I send you a copy of the report of the officer who made the tests at the Watertown Arsenal of the United States. The testing machine is the one designed and built by Mr. Emory for the United States Government, under a special appropriation made by Congress for the purpose. The machine itself is accepted by all engineers and architects in this country as infallibly accurate. Its range is from the pulling asunder of a bar of steel with a pull of 800,000 pounds, to the breaking by extension of a horse-hair, and it gives exactly the strain which breaks either specimen.

Mr. Davis is in error in saying that no bricks have ever made so good a showing as the above. Over twenty-four years ago, while erecting the extension of the United States Capitol, I built a testing machine with which I made many tests of materials, some of which have found their way into the American handbooks of construction; and I then found and tested bricks which broke at 10,000 pounds to the square inch. The specimens broken were cubes of  $1\frac{1}{2}$  to 3 inches on the edges.

Very respectfully your obedient servant,

M. C. MEIGS, Quartermaster-General  
U.S. Army Retired.  
Architect, Pension Building.

#### Artificial Paving.

SIR,—We notice in your impression of August 30, under the head of “Notes on Novelties,” a notice of “Artificial Granite Paving,” in which, after expressing your surprise that artificial or concrete pavings (taking the term in its widest sense) have found so little favour in the eyes of local boards and vestries, you proceed to state that you consider the reasons are perhaps twofold, viz.:—First, that the very few who have introduced this substance have confined their operations to stables and such places; and secondly, that when brought out as a footpath for streets it was laid down in a manner not suited for such requirements.

We assume that you do not include the “Patent Victoria Stone” in the list of concrete pavings, and you are right in so doing; for although this material at one stage of its manufacture is a concrete, when the process is complete it becomes the nearest approximation to nature that has yet been attained, with perhaps the single exception of Ransome’s stone, so extensively used many years since for architectural purposes. But inasmuch as members of local boards and vestries are apt to put down all artificial or manufactured pavings in the same category, we shall be obliged, if you allow us, to state, for the information of your readers, should they consider us one of “the very few,” that our paving has during the last eighteen years been almost exclusively used for paving London footways, and that during that period over eighty miles taken at seven feet wide have been laid within the metropolitan area, and not to any considerable extent in “stables and yards.”

We can quite endorse what you say as to the difficulties of introducing novelties to public bodies, as, when the “Victoria Stone” was first introduced, several vestries in London refused the offer of an experimental length of paving free of cost. Such was the prejudice at that time against anything but the old-fashioned laminated York stone.

In speaking of “granite,” you doubtless mean any rock of igneous origin (and not, in its strictest sense, a composition of quartz, felspar, and mica) is undoubtedly a suitable aggregate when thoroughly clean for making concrete, but to say that this, when mixed with Portland cement, “must necessarily make as hard a footpath as anything we can use” is equivalent to stating that Portland cement at once attains its ultimate strength, and that any induration is unnecessary; this, we need hardly remind you, is not the case. The late Rev. H. Highton, the inventor of “Victoria Stone,” and an able chemist, seeing the necessity of some quicker mode of induration, struck upon his comparatively cheap mode of silicating, which is used in our works to this day, and we point to our paving for the practical results.

If the material you describe can be laid at 3s. 6d. per yard super, including excavation and foundation where necessary, it certainly has the merit of cheapness, but until you can insure good cement being delivered on to the ground, properly manipulated there, you can never get a good concrete path suitable for even suburban districts.

Yours faithfully,

THE PATENT VICTORIA STONE COMPANY  
(per Harry Rogers).

283A Kingsland Road:  
Sept. 3, 1884.

The gold medal of the International Exhibition at the Crystal Palace has just been awarded to us for “Victoria Stone” paving and general masonry.

Watertown Arsenal, Mass.: December 16, 1882.

JOHN G. BUTLER,  
Captain of Ordnance, Commanding.

## WORKS IN PROGRESS.

**Church Clocks.**—On August 25, a large Cambridge quarter clock, with two outside dials, was set going in the parish church, Middleham, North Yorkshire, in the presence of the rector and churchwardens and a large company of the inhabitants, by Mr. John Topham, Middleham House, the clock being given by Sir Thomas Topham, Coverham Abbey. The following Wednesday another large Cambridge quarter clock, with four 6-foot dials, and striking upon the new peal of fine bells lately fixed in All Saints' parish church, Skelton, North Yorks, the ancient residence of the De Bruce family. This clock has been presented by Mr. J. T. Wharton, J.P., of Skelton Castle. Both the clocks—Middleham and Skelton—were manufactured by Messrs. William Potts & Sons, of Guildford Street, Leeds, who are also fixing another clock at Burton-in-Lonsdale Church, near Lancaster, and restoring the block and chimes of Beverley Minster, and fixing a new large dial.

**The American Elevator Co.,** of 38 Old Jewry, Cheapside, E.C., have just received the contract for a first-class passenger lift, to be erected in the Victoria Hotel, Sheffield, of which Messrs. Mills & Murgatroyd, of Manchester, are the architects.

## ARCHÆOLOGY.

**Remains of a Roman Villa at Lincoln.**—A few days ago some miners who were excavating a new mining shaft in the Greetwell Fields came upon the remains of a Roman villa. From the nature of the diggings, so much unavoidable damage had been done to the remains that all that is at present to be seen are some walls, a well seven feet in diameter, and portions of tessellated pavements, broken tiles, and pottery. This much, however, is clear, that between two walls running a considerable distance south and north, and fifteen yards apart, several apartments existed, as indicated by walls, tessellated pavements, and large flat tile pavements. From these apartments steps led down to a room which probably was a bath-room, and under the bath-room is a well, still in a comparatively good state of preservation. The tesserae of the upper apartments are chiefly of red and blue brick and white stone, but the tesserae of the bath-room are white, and are apparently made of hard concrete. All the tesserae are about an inch and a half square, and were laid on a deep layer of the ordinary Roman concrete. The large flooring tiles are red, and bear an impressed checkered pattern. On clearing out some of the rubbish from the well, fragments of wall plaster, probably of the bath-room, were found; these fragments show that the apartment, or apartments, must have been beautifully painted and decorated. The colours used in the painting were red, yellow, blue, green, and white, and the decorations were evidently executed with the greatest neatness and precision. On one piece of plaster is the picture of a swallow, well drawn and painted. The house must have been the property of a Roman gentleman of taste and opulence. The site was well chosen, but in consequence of the villa being built on the brow of a hill, the lower rooms were on different planes. Doubtless, if careful diggings were extended on either side of the mining trench, other Roman discoveries of a valuable character might be made.

## ENGINEERING WORKS.

**The Liverpool Docks.**—Mr. G. F. Lyster, engineer to the Mersey Docks and Harbour Board, has just published his annual report showing the general state and progress of the dock works at Liverpool and Birkenhead, together with the expenditure in his department for the year ended the 1st of July last. The report refers in detail to the work done during the year at the various docks of the estate both in Liverpool and Birkenhead. With regard to the high-level coal railway extension, it is stated that the additional accommodation for the shipment of coal is now completed and ready for immediate use. It consists of a high-level system erected on the north quay of the Bramley Moore Dock, in extension of that now in use on the east quays of the Wellington and Bramley Moore Docks. It is 908 feet in length by 63 feet in width, and is provided with a comprehensive system of railways, sidings, turntables, and capstans, and also with five 25-ton cranes for loading ships, and these are actuated by hydraulic power. In regard to the Sub-Mersey Railway Tunnel, the report stated that the drainage heading was so far completed in the early part of the year that a party of those interested in the undertaking walked through it on January 17, and the main tunnel is rapidly advancing towards completion. The total amount expended on the entire estate for the year had been 514,287*l.* 1*s.* 11*d.*, of which 430,466*l.* 2*s.* 5*d.* were for the Liverpool side of the river, 65,242*l.* 14*s.* 8*d.* for Birkenhead, while the conservancy expenses amounted to 4,189*l.* 13*s.* 4*d.*, and the official charges to 14,388*l.* 11*s.* 6*d.* During the year there had been expended on the new dock works at the North End 20,036*l.* 6*s.* 4*d.*, in addition

to the original outlay of 2,396,751*l.* 15*s.* 7*d.* The river craft dock had cost 11,408*l.* 4*s.* 2*d.* in the course of twelve months. The new works at the South End had during the year entailed an expenditure of 82,176*l.* 16*s.*, while the deepening of the new South Dock and sills had incurred an additional cost of 7,739*l.* 3*s.* 5*d.*

**Kirkcaldy Harbour.**—Sir John Coode, C.E., has just sent in his report, with an accompanying plan of the proposed new harbour for Kirkcaldy. According to the plan the harbour and dock works will be on a large scale, occupying the space of Ravenscraig rocks on the east to the pier of the present harbour to the west. The entrance to the outer harbour, which will be opposite the floorcloth works of Messrs. M. Nairn & Co., will have a depth of 10 feet at low water of spring tides—the entrance itself being 1,500 feet from the Castle rocks. The wet dock will cover an area of 8 acres, being thus 2½ acres larger than Burntisland Dock. The depth over the sill at the dock gates will be 21 feet at high water of neap tides. The dock occupies a position immediately in front of Messrs. Hutchison's malting premises. Sir John Coode estimates that these extensive works, capable of accommodating the largest class of merchant vessels afloat, will be obtained at an expenditure not exceeding 300,000*l.*

**Below Bridge Communication.**—A committee, consisting of Mr. Green, chairman; Mr. J. Brand, City Comptroller; and other gentlemen, appointed to inspect various large bridges throughout the country with a view to recommend to the Corporation of London the best style of bridge with which to span the Thames below London Bridge, have lately visited Leith. Mr. Whyte, dock superintendent, explained to the committee the construction of the Victoria Swing Bridge, which crosses the harbour, and connects the Victoria and Albert Docks. This bridge, which has two lines of rails upon it, and is worked by hydraulic power, was built by Sir William Armstrong, of Newcastle, at a cost of about 28,000*l.*

## CHURCH BUILDING AND RESTORATION.

**Lochgilthead, N.B.**—The memorial-stone of the new parish church was laid on the 21st inst. by Mr. C. Dalrymple, M.P. The building stands on the site of the old church, and will have seats for 400 worshippers. The estimated cost is 2,300*l.* Mr. John Honeyman is the architect.

**Campden Church.**—The parish church of Chipping Campden has been reopened after restoration of the interior. The exterior was renovated a few years ago, and a little over 1,000*l.* has now been spent in levelling and renewing the floor, providing new seats and choir stalls, removing and improving the organ, and other work. The present restoration has been carried out from designs of Messrs. Waller, Son, & Wood, of Gloucester.

**Leyburn.**—The memorial-stones of a Wesleyan chapel have been laid. The chapel will be in Early English style, and will accommodate about 300 persons. There is a schoolroom behind to accommodate 100 children, with two classrooms, and above there is the organ gallery. The internal woodwork will be of pitch pine, with open seat ends, the ceiling being boarded and panelled and circular pointed. Mr. C. Anderson, of York, is the architect, and the contractors are Mr. Jas. Peacock, brick and stonework; Mr. Alfred Sanderson, joiner's work; Mr. T. T. Dobson, plumber; and Mr. Thomas Horner, painter. The cost will be about 1,500*l.*

**Preston Candover.**—The foundation-stone of a new church has been laid. The site of the church, which is to be erected from plans prepared by Mr. A. W. Blomfield, is at the junction of the Wield and Alresford roads, in the centre of the village. The church will be in Early English style, built of flints, with red brick and stone dressings and windows. It will consist of a nave, chancel, north aisle, and vestry, and the entrance will be by a porch approached by a flight of steps. The architect's design includes a tower and spire, reaching to a height of 100 feet. The builders are Messrs. J. & E. Dyer, of Alton. The estimated cost is 3,300*l.*

**Stebbing.**—The parish church of St. Mary the Virgin, Stebbing, has been reopened after partial restoration. The tracery of the aisle windows, on the outside especially, being of the perishable clunch, still need restoration. Besides the aisle windows, the chancel, tower, and south porch remain untouched, all much in want of the restorer's hand. About 2,000*l.* more are wanted to complete the restoration. Mr. Woodyer is the architect, and Mr. S. C. Parmenter, of Braintree, the contractor.

**Beddingham.**—The parish church of St. Andrew has been reopened after extensive repairs to the walls and a complete renovation of the north aisle, nave roof, and belfry tower interior, carried out under the direction of Mr. W. White, F.S.A.

**Bolton.**—St. Matthew's Church has been reopened after renovation. The ceilings of the nave and transepts are coloured in distemper, the panels in each case being filled in with ornaments of a bluish grey. The timbers of the roof have been cleaned and varnished, and the coronæ and gas brackets repainted and gilded, whilst a new ornamental gas bracket has been placed

under the western window. The walls are painted in oil, finished with colours of a creamy hue, which brighten up the whole and aid the light considerably. The ornamentation on the walls is very chaste, the predominant tint being a brownish red, which has a pleasing effect. The spandrels between the arches are filled in with quatrefoils, in which are introduced floral devices, and beneath these are neat stencil bands. Ornamental bands are also carried below the spring of the clerestory windows, over the arches, under the frieze, and below the string-course beneath the windows. A bold ornamental design runs round the walls of the aisles and transepts level with the capitals of the columns, and the same pattern is introduced at the level of the frieze on the west wall of the nave and the end walls of the transepts. Plain bands of colour are run round the arches, those to the western end having ornamental finials. The lower portions of the walls are adorned with a dado of greenish grey, the ornamental pattern on the top forming a pleasing contrast to the quiet tone of the walls. The same designs are introduced in the "Green" chapel. The chancel ceiling and the walls are painted in oils, and the panels of the ceiling are very beautifully decorated in gold and colours, with alternate quatrefoils of pale red and blue. The walls are ornamented with a neat design, and have besides an elaborate dado. On the cornice is the motto "Glory to God in the highest, and on earth peace, goodwill towards men." The designs for the decorations are the work of Messrs. T. D. Barry & Sons, of Liverpool, the architects of the church, and the work has been carried out by Mr. James Gregson, of Bolton.

### NEW BUILDINGS.

**Grangemouth.**—The memorial-stone of the new Town Hall has been laid. The principal front will have a frontage of 67 feet. The height from ground to top of parapet will be 40 feet 6 inches. The style adopted is Classic, after the Greek school. The ground storey will be built of polished ashlar, with horizontal channels. A moulded cornice, with dado over, will form the base of the upper storey. There will be a public entrance from the west side, which will give immediate access to the public office. The gallery, council chambers, and other two rooms will form the upper floor of the front portion of the building. The area of the hall will accommodate 550 and the gallery about 320—in all, 870. The small hall or upper room will seat upwards of 100 persons. The estimated cost is 4,600*l*. Mr. Black, of Falkirk, is the architect.

**Hawick.**—The memorial-stone of a cottage hospital has been laid. The hospital occupies a site in Buccleuch Street, and, when finished, will have accommodation for fourteen beds, besides having improved baths and all requisite hygienic arrangements. The funds for the erection of the building have been provided by public subscription and otherwise, considerable support being given by the late Duke of Buccleuch and the Scott Bequest Fund, the latter providing for an extensive dispensary. Mr. McLachlan, Edinburgh, is the architect.

**London.**—On Monday morning, Mr. Thomas Kellby, the Master of the Butchers' Company, formally laid the foundation-stone of the new hall of the guild in Bartholomew Close. The first Butchers' Guild was established in 1180, and their first charter was granted by James I. in 1606. Owing to fire and City improvements, the Butchers' Company has been tossed about from pillar to post, but now they have settled down on ground situated but a few yards from where their original home stood. The foundation-stone has the following inscription:—"This stone was laid upon the first day of September, 1884, by the Worshipful Master, Thomas Kellby, Esq.; Alexander Peebles, architect; B. E. Nightingale, builder; H. J. V. Philpott, clerk to the company."

### SCHOOL BUILDINGS.

**Glasgow.**—An addition has been made to the Thomson Street schools, chiefly with the object of providing accommodation for the teaching of science and art classes. The new premises consist of a wing two storeys in height, containing in the lower flat an infant schoolroom 67 feet by 32 feet, and in the upper a drawing-class room and laboratory measuring together 78 feet by 32 feet. Accommodation is provided for 507 pupils—247 infants and 260 senior students. The plans for the extension were prepared by Mr. Frank Burnet, architect.

**York.**—The foundation-stone of new Roman Catholic day schools in York has been laid. The interior of the building will be of the best workmanship. The floor of the schoolroom will be paved with blocks of pitch pine, and both rooms will have a dado of cream-coloured glazed bricks. There will be two approaches to the school, one for boys, and one for girls, and the boys and girls will have a separate playground. The cost will be rather more than 2,000*l*. Messrs. Goldie, Child & Goldie, of London, prepared the plans, and the contract is being carried out by Messrs. Biscomb & Sons, of York.

**Hucknall Torkard.**—A new block of Sunday-schools connected with the Baptist chapel has been opened. The schools have been erected and furnished at a cost of over 1,000*l*., the main cost of the structure having been borne by Mr. J. Nall, of Papplewick Grange, and Mr. J. Hinners, of Southport. The building has been designed by Messrs. Booker, of Nottingham, and is excellently adapted for the purposes of a Sunday-school. It comprises a large central room and a suite of six classrooms, all opening into and by means of large windows commanding a full view of the central hall. Mr. J. Munks, of Hucknall, is the contractor, and the work has been executed in simple Gothic style in harmony with the adjoining chapel, the walls being of brick with stone facings.

**Kelsall.**—A Wesleyan chapel and school has been opened. The buildings, which are in the Gothic style, are of stone, rock pitched face, with Eddisbury stone dressings. They consist of a chapel, two vestries, and two schoolrooms. The chapel is 53 feet by 32 feet, and contains a gallery on the south side which will seat about eighty persons, and which is reached by a flight of stairs at either end. There are five sets of principals of red deal with perforated trefoils and rings. The strength of the building is enhanced by five iron rods which run across. On either side of the pulpit there is a narrow stained glass window, and a window on the south side is of "cathedral tinted" glass. The principal entrance to the chapel is on the south side. Each of the two vestries, which are reached by a door on either side of the rostrum, is 18 feet square. The principal schoolroom is 35 feet by 18 feet, and the infants' room is 15 feet by 10 feet. The school and chapel have been so designed that, when occasion requires it, a partition is removed and the school becomes part of the chapel. The building is heated by apparatus supplied by Mr. Thomas Jones, of Manchester. Mr. John Wills, of Derby, is the architect, and the contractors are Messrs. G. & H. Wright and Isaac Johnson, all of Kelsall.

### GENERAL.

**Her Majesty** has conferred the distinction of a diploma upon the members of the Royal Institute of Painters in Water-Colours.

**Mr. C. Burton Barber** has been awarded the prize of 50*l*. and a gold medal offered by the committee of the Welsh National Eisteddfod, for the best picture in oil illustrative of an incident in Welsh history. The subject is *Gelert*, and the picture is now on view at the autumn exhibition in Liverpool.

**Mr. Boehm, R.A.**, is to receive the commission for the bronze statue of the late Mr. Bass, which is to be erected in Derby.

**Mr. J. E. Reid's** picture, *The Rival Grandfathers*, which was exhibited this year at the Grosvenor Gallery, has been purchased by the Liverpool Corporation.

**Mr. Alma Tadema, R.A.**, the president of the Royal Birmingham Society of Artists, arrived in Birmingham on Wednesday, and was present at the private view of the society's exhibition. Mr. Tadema is the guest of Mr. J. A. Chatwin, the vice-president of the Society of Artists.

**The British Association** will meet next year in Aberdeen.

**The Awards** of the juries of the Health Exhibition will not be announced until next month.

**Mr. H. Coghill**, Newcastle-under-Lyme, has intimated that if the proposed scheme of adopting the Free Libraries Act and erecting public baths in Newcastle is carried out in its entirety, he will give 1,000*l*. towards the cost.

**The Duke of Portland**, it is stated, has resolved to spend 10,000*l*. in the improvement of Troon harbour.

**Islington Old Churchyard** is to be converted into a public recreation ground, at an estimated cost of 1,100*l*.

**The Manchester City Council** have decided to rebuild the Corporation stables in Water Street at a cost of 7,200*l*.

**The City of Bristol** on Monday entered into possession of the Avonmouth and Portishead Dock undertakings, which have been purchased for 800,000*l*. They will be amalgamated with the Bristol Docks, already the property of the citizens. The purchase-money is to be paid in Corporation bonds bearing interest at 3½ per cent.

**M. Emile Trélat**, the French architect, read a paper at the International Sanitary Congress at the Hague, upon the ventilation of houses. He advocated the use of a bright open fire, with a plentiful supply of cold air taken direct from the outside of the buildings.

**The Provisional Committee** of the Manchester Ship Canal have met in Manchester to consider the alternative route of the canal to avoid the Mersey estuary. No definite conclusion was arrived at, the plans not being yet fully before the committee. Instructions were issued to the engineer to press forward the completion of the plans as quickly as possible.

## CONTRACTS, COMPETITIONS, AND TENDERS.

LONDON, SEPTEMBER 6, 1884.

### TENDERS, ETC.

*\*\* As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, 175 Strand, London, W.C., not later than 3 p.m. on Thursdays.*

*\*\* Correspondents, when writing to notify an extension of time, or an alteration of the date of sending in Competitions or Contracts, are requested in their letter of advice to write at the head of the required change—"Contract Supplement to THE ARCHITECT."*

### COMPETITIONS OPEN.

**BIDEFORD.**—Sept. 22.—The Trustees of the Bideford Bridge Trust invite Competitive Designs for the Erection of a Block of Buildings suitable for a Post Office on site of Premises in High Street. Premiums of 20*l*. and 10*l*. The cost of carrying out any of the Designs not to exceed 300*l*.

**BOMBAY.**—Nov. 6.—The Municipal Commissioner of Bombay invites Designs and Estimates for a New Municipal Hall and Offices, which must be sent to his Office by Twelve noon, on Nov. 6. A Premium of 5,000 rs. will be given for the Design most approved of by the Commissioner, with the assistance of a Committee of the Corporation; 3,000 rs. for the second, and 2,000 rs. for the third. The total cost of the buildings is not to exceed 5 lacs (5,00,000 rs.). Mr. E. C. K. Ollivant, Municipal Commissioner's Office, Bombay, or at Messrs. E. W. & R. Oliver, 1 Corbet Court, Gracechurch Street, London.

**LONDON.**—Plans are invited for the Erection of School Buildings, Classrooms, Lavatories, and Outbuildings for 200 Boys. Mr. Geo. H. Hawley, Clerk to the Governors of the Endowed Schools, Longton.

**REDRUTH (CORNWALL).**—Sept. 13.—*School.*—The Redruth School Board offer a Premium of 25*l*. for the best Plans (Elevation and Detailed Drawings), to be selected by themselves, for a School, to be erected at Trewirgie, Redruth, to accommodate 700 Children (350 Boys and 350 Girls and Infants). Total cost not to exceed 3,500*l*. Mr. Charles Bowden, Clerk, Heanton Place, Redruth.

**STOCKPORT.**—Oct. 1.—Designs are invited for Public Baths. Premiums of £50, £30, and £20. Mr. Walter Hyde, Town Clerk, Stockport.

### CONTRACTS OPEN.

**BLACKBURN.**—For Building Church. Mr. W. S. Varley, Architect, 16 Richmond Terrace, Blackburn.

**BLACKROD.**—Sept. 8.—For Building Cemetery Chapel, &c. Mr. R. Knill Freeman, Architect, Bolton-le-Moors.

**BRADFORD.**—Sept. 9.—For Construction of Station. Plans at the Engineer's Office, Hunt's Bank, Manchester.

**BRECON.**—Sept. 6.—For Building House. Messrs. Browne & Gill, Architects, 1 Fountain Buildings, Bath.

**CAMBRIDGE.**—Sept. 11.—For Building Hospital. Mr. W. J. Bowyer, Town Surveyor, Guildhall, Cambridge.

**CARMARTHEN.**—Sept. 12.—For Building Schoolroom to Baptist Chapel. Mr. George Morgan, Architect, 24 King Street, Carmarthen.

**CLEGGAN.**—Sept. 24.—For Construction of Basin, Wharves, Groin, Extension of Pier, Deepening Harbour, &c. Mr. W. B. Soady, Secretary, Office of Public Works, Dublin.

**CYMMER.**—Sept. 11.—For Building Board Schools. Mr. Batchelor, Architect, Rotunda Buildings, Cardiff.

**DARLINGTON.**—Sept. 9.—For Re-seating St. Cuthbert's Church. Mr. Francis Parr, Architect, 6 Duke Street, Darlington.

**DEWSBURY.**—Sept. 15.—For Building Five Houses, Savile Town. Mr. H. Holtom, Architect, Bond Street, Dewsbury.

**DUBLIN.**—Sept. 10.—For Additions to Mercer's Hospital. Messrs. J. C. & H. C. Brett, Architects, 49 Dame Street, Dublin.

**GLASS.**—Sept. 13.—For Building Dwelling-house. Messrs. Matthews & Mackenzie, Architects, 255 Union Street, Aberdeen.

**GLYNCORRWG.**—Sept. 11.—For Building Board Schools. Mr. Batchelor, Architect, Rotunda Buildings, Cardiff.

**GORLESTON.**—Sept. 17.—For Building House and Shop. Mr. W. B. Cockrill, Architect, Glencoe House, Gorleston.

**GREENHEAD.**—Sept. 6.—For Building Methodist Church. Mr. Joseph Shields, Architect, Blackett's Buildings, Sunderland.

**HALIFAX.**—Sept. 6.—For Building House and Shop. Mr. Joseph Wilson, Architect, 222 Pellon Lane, Halifax.

**HALIFAX.**—Sept. 6.—For Building Engine-house and Chimney at the Albert Reservoir. Mr. Escott, Borough Surveyor, Town Hall, Halifax.

**HALIFAX.**—Sept. 8.—For Extension of Passenger Station. Plans at the Engineer's Office, Hunt's Bank, Manchester.

**HAMMERSMITH.**—Oct. 2.—For Rebuilding Superstructure and Strengthening Hammersmith Bridge, Construction of Temporary Bridge, &c. Sir J. W. Bazalgette, Spring Gardens, S.W.

**INVERURIE.**—Sept. 13.—For Erection of Buildings at Inverurie Mills. Messrs. Jenkins & Marr, Architects, 16 Bridge Street, Aberdeen.

**KEIGHLEY.**—Sept. 10.—For Pulling Down and Rebuilding Buildings in Longcroft. Mr. W. H. Hopkinson, Borough Engineer, Low Bridge, Keighley.

**KIDDERMINSTER.**—For Building Offices and Warehouses. Mr. J. M. Gething, Architect, 7 Church Street, Kidderminster.

**KNOCKADOON.**—Sept. 17.—For Construction of Boat Slip and Platform, Rock Excavation, &c. Office of Public Works, Dublin.

**LEICESTER.**—Sept. 11.—For Building Shops and Offices. Mr. E. Lidiard James, Architect, 119 Cheap-side, E.C.

**LIMERICK.**—Sept. 22.—For Building the St. Vincent of Paul National School. Messrs. Nash & Son, Land Agents, 85 George Street, Limerick.

**NEWCASTLE-ON-TYNE.**—Sept. 6.—For Building Detached Residence. Messrs. Newcombe & Knowles, Architects, 89 Pilgrim Street, Newcastle.

**NEWCASTLE-ON-TYNE.**—Sept. 30.—For Clearing Site and Building Offices for the Tyne Improvement Commissioners. Mr. J. J. Stevenson, 18 Queen's Road, Bayswater, W.

**PERTH.**—Sept. 26.—For Enlargement of the General Station. Messrs. Blyth & Cunningham, C.E., 135 George Street, Edinburgh.

**PEWSEY.**—For Erection of Farm Buildings, Cottages, and Stables and Additions to Farmhouse. Mr. J. C. Rose, Sunny Hill, Pewsey.

**SHIPTON-UNDER-WYCHWOOD.**—Sept. 6.—For Building Beaconsfield Hall. Mr. T. Brookes, Shipton, Chipping Norton.

**ST. BUDEAUX.**—For Enlargement of Schools. Mr. A. Norman, Architect, 3 Buckland Terrace, Plymouth.

**STOCKTON.**—For Building House. Mr. John Rodham, Surveyor, 16 Finkle Street, Stockton.

**STRATFORD.**—Sept. 23.—For Building Police Court and Offices. Mr. Lewis Angell, C.E., Town Hall, Stratford, E.

**STROUD.**—Sept. 20.—For Building Post-Office. H.M. Office of Works, 12 Whitehall Place, S.W.

Note Trade Mark.

**GRUNDY'S PATENT  
WARM-AIR  
VENTILATING FIRE GRATE.**

The novelty, superiority, and advantage of this patent consist in the heating surface being greater than any other Fire-grate introduced to the public. It is very simple in construction, and is made in the form of a Stove, the back of which is semicircular in shape, with gills behind and smoke-nozzle on top, all cast in one piece. The same can be attached to any design of a Register or Stove front. It is very suitable for schools, class-rooms, waiting-rooms, hospitals, offices, dormitories, and dwelling-houses, from the cottage to the mansion. Design and specification post free on application.

**TESTIMONIALS.**

"9 Victoria Chambers, Westminster, S.W.

"June 10, 1884.

"SIR,—I have much pleasure in testifying to the efficiency of your patent Warm-Air Fire Grate. It has been very successful, and given every satisfaction where I have used it.

"Yours, &c.

"JAMES WEIR, F.R.I.B.A.

"To Mr. Grundy."

"Baptist Chapel, Clapham Common, London. Richard Webb, Pastor, 10 Grafton Square.

"February 15, 1884.

"DEAR MR. GRUNDY,—I have pleasure in testifying to the excellency and efficiency of your patent Fire-Grate. It is the most charming invention for heating a large room I have ever known. I shall have pleasure in showing it to anyone who wish to have their schools or rooms pleasantly and efficiently heated."

From James Garry, Esq., Architect, West Hartlepool, July 1884.

"DEAR SIR,—I have very great pleasure in stating that the first stove, or patent warm-air ventilating fire grate, adopted by me in school at Seaton, and a second in a Cocoa Palace, have given such satisfaction that I now order eleven to be inserted in New Upper Grade Schools in course of erection at West Hartlepool. They are the most economical, efficient, and easily managed stove at present before the public.

"Mr. John Grundy."

Apply to JOHN GRUNDY, 30 Duncan Terrace, City Road, London.

# BELL'S ASBESTOS.

## BELL'S ASBESTOS FLOORING FELT.

This article is manufactured from specially prepared Asbestos fibre, and by its use any building can be rendered comparatively fireproof at a very small cost. This material should be used as a substitute for brown paper under the carpet, and it can be taken up and relaid as often as required; it may be laid between the flooring boards, on the ceiling before plastering, and on the walls. Doors of pine or other wood should be so constructed as to have a sheet of the felt in the centre, so that either side being burned the other remains intact. In houses so protected fires would be localised to the rooms in which they originate. Asbestos felt, being a non-conductor of heat, is superior to any other sheathing, and used under slates has no equal. It yields no dust, lies quite flat, is soft to the tread, and its low cost places it within the reach of everybody. Made in rolls of 36 inches wide.

**BELL'S ASBESTOS BOILER AND PIPE COVERING COMPOSITION** for coating every class of steam pipe and boiler. Non-combustible, and easily applied when steam is up; adheres to metals and preserves them from rust; prevents the unequal expansion and contraction of boilers exposed to weather; covers 50 per cent. more surface than any other coating, and is absolutely indestructible. It can be stripped off after many years' use, mixed up again with 20 per cent. of fresh, and applied again. The composition is supplied dry, and only requires to be mixed with water to the consistency required for use.

A horizontal boiler, 17 ft. 6 in. long, 15 H.P., gave the following results:—

Temperature on Plates .. .. .	186 deg.
"          "          Covering .. .. .	94 "

One ton of coal was saved per week, and, although the fire was raked out every evening 20 lbs. of steam were in the boiler next morning.

The following testimonial refers to this covering:—

Dear Sir.—It may interest you to know that we save exactly 40 per cent. in fuel through using your covering.—Yours truly,  
W. SANTO CRIMP, C.E., F.G.S.

**BELL'S ASBESTOS PAINT**, for floors, stairs, and all interior woodwork, to prevent the spread of fire. This paint is especially useful in cotton mills, and in fact in all factories and buildings exposed to risk from fire. It is quite free from poisonous ingredients, and is both easily and cheaply applied. Bell's Asbestos Paint has, on several occasions, done great service in preventing the loss of life and property. The great fire in Buchanan Street, Glasgow, in November last, produced the following testimony to the value of this material:—

Offices of the *Glasgow Herald*, the *Weekly Herald*, and the *Evening Times*.

Mr. John Bell.  
Sir,—As one of the means that helped to save our buildings extending from Buchanan Street to Mitchell Street from the recent great fire, I think it fair to say that your Asbestos Paint, which was applied to the outside hoist of the *Evening Times* case-room and other portions, gave valuable proof that it materially aided in resisting the flames from the immediately adjoining tenement while the fire was rapidly destroying it and threatening us in the most serious form. Since the fire, and to assure myself further of the value of the Asbestos Paint as a fire-resister, I placed a piece of wood, with your paint put on more correctly than in our case, into one of our furnaces, with the result that it was brought out without a fibre of the wood being touched, while similar pieces of wood, thrice coated with Irish Lime, at once got into a flame.—Yours truly,  
(Signed) ALEX. SINCLAIR.

**BELL'S ASBESTOS SASH-LINE CORD** is unaffected by heat and damp, and renders unnecessary the use of metallic wire and chains. Ropes made in the same form have great tensile strength, and being indestructible by fire are of incalculable value for fire escapes.

## BELL'S ASBESTOS.

The goods of this house are of the highest quality only, and no attempt is made to compete with other Manufacturers by the supply of inferior materials at low prices. All orders must be sent direct to the undermentioned depôts, and not through agents or factors.

**BELL'S ASBESTOS AND INDIA-RUBBER WOVEN TAPE AND SHEETING** for making every class of steam and water joint. It can be bent by hand to the form required, without puckering, and is especially useful in making joints of manhole and mudhole doors on boilers; also for large "still" joints, where boiling fat and steam have to be resisted. It is kept in stock in rolls of 100 feet, from  $\frac{1}{4}$ -in. to 3-in. wide, and any thickness from  $\frac{1}{8}$  in. upwards. Manhole covers can be lifted many times before the renewal of the jointing material is necessary. The same material is made up into sheets about 40 in. square, and each sheet bears the trade mark, without which none is genuine. It is very necessary to guard against imitations of this useful material, and to secure themselves against being supplied with these less useful articles at my price, users are recommended to see that every 10-ft. length of the Asbestos Tape purchased by them bears the trade mark.

**BELL'S ASBESTOS CEMENT** for the backing of firebricks and furnaces. The use of this fireproof material saves the expense and annoyance occasioned by the repairs so constantly required in the firebricks and kitchen ranges of private houses. Any labourer accustomed to handle other cements can apply this.

**BELL'S ASBESTOS BOILER PRESERVATIVE**.—This useful mixture, by absorbing the free oxygen that is in the water, entirely checks pitting and corrosion. It also disintegrates incrustation so immediately as to prevent its adhering to the plates. Not only is a great economy of fuel effected by keeping boilers clean, but the risk of having the plates burned is thereby obviated. It has been computed that 1-16th inch thick of incrustation causes a waste of 15 per cent. of coal;  $\frac{1}{4}$  inch thick, 60 per cent.; and  $\frac{1}{2}$  inch, 150 per cent. Thus the Preservative avoids the great risks which are inseparable from scaled plates, lengthens the life of a boiler, and covers its own cost a hundredfold by economy of fuel. It is entirely harmless, and has no injurious action on metals. It can be put into the feed tank or boiler, as may be most convenient. Sold in drums and casks bearing the trade mark, without which none is genuine.

**BELL'S PURE ASBESTOS CLOTH**, for protection against the spread of fire. Iron curtains warp, and in the great emergency of fire will often be immovable. Asbestos cloth, being incorruptible, will remain strong and flexible for an indefinite period, and will stay the progress of a fire and the passage of smoke longer than any other known material. This cloth is also extensively used in Maignen's unequalled water filters, for which a gold medal and diploma of honour were awarded by the Special Commission appointed by Her Majesty's Government to receive the reports of the International Juries at the Fisheries Exhibition. By special arrangement with Mr. Maignen, his filters for houses, factories, and towns are supplied by this firm.

**BELL'S ASBESTOS BLOCK GAS FIRES**.—The Asbestos Block Gas Fire is formed by placing inside the ordinary grate a hollow block (burner), composed of Asbestos, and perforated. An iron sole-plate, with a single gas burner, is fixed at the bottom of the block. After being lighted a short time, both the block and asbestos fuel throw out intense heat.

**BELL'S ASBESTOS FUEL** for gas fires. This genuine Asbestos Fuel is composed of the finest hand-picked Asbestos, and its weight is about half that of any other Asbestos fuel.

**BELL'S SPECIAL LONDON-MADE ASBESTOS MILLBOARD**, for dry steam joints, made of the best Asbestos fibre, is well-known for its toughness and purity, and is absolutely free from the injurious ingredients frequently used to obtain an appearance of finish, regardless of the real utility of the material. Made in sheets measuring about 40 in. square, from 1-64th in. to 1 in. and  $\frac{1}{2}$  millimetre to 25 millimètres thick. Each sheet bears the Trade Mark.

# The Architect.

## A CHAPTER OF PRACTICAL CRITICISM: THE WAR OFFICE AND ADMIRALTY.

OW that the selected design for the new War Office and Admiralty is well known to the architectural profession, and that the position won by its authors may be assumed to be secure, we may appropriately undertake to submit to our readers a few more observations upon the salient points of its artistic composition, as a study in criticism. We take, of course, the published view towards St. James's Park; and we will ask leave to refer also to one of the other designs, that of Messrs. STARK & LINDSAY (in our last week's issue), for the sake of illustrating some of our remarks by means of comparison.

Messrs. LEEMING's primary motive of composition, as regards this aspect of their building, may be thus described. One great comprehensive mass occupies the whole site in front of the line of Spring Gardens and the Horse Guards; from which a wing is thrown out to cover the extra space at the south-east corner. Messrs. STARK & LINDSAY's primary motive is virtually the same.

Upon this basis Messrs. LEEMING mark the angles of their principal mass by three campanili; there are necessarily four angles, and one of them, like *Punch's* "one poor tiger that hadn't got a Christian," has not got a campanile. Now, if there be any reason for this, the designers are quite entitled to argue for its sufficiency; but if it be only an oversight, then criticism may run thus. The campanili are lofty; even from the somewhat close point of view from which the perspective drawing is made the third shows its summit distinctly, and the further the spectator goes across the park—and he can go a very long way—the more must this feature come into view, and the absence of its fellow provoke inquiry. Whether it is enough to point to the symmetrical disposition of the façade of the wing, in pursuance of which the inner corner in question is marked by a different feature of the same sort, a reflection of the lantern which emphasises the outer corner, we leave the reader to consider; but we may perhaps be allowed to ask why the middle of the length of this wing should have the domed pavilion introduced at all, and whether it is not the southward wall over the Horse Guards, if any, that ought to be made symmetrical, as the end "front" of a mass of which the return front is but a flank?

In this respect Messrs. STARK & LINDSAY treat the case differently. They mark by campanili, or towers, only the two front angles of the great mass, and there is no third to suggest the want of a fourth. The treatment of the flank of the wing, also, has a certain advantage, in being apparently, although not really, a lower building. But here again let the reader consider whether the symmetrical composition of this flank wall as an independent façade is not objectionable. In fact the treatment of a large building on the plan of making each wall a principal front is surely productive of confusion in the mass; and we may go so far, if only experimentally, as to inquire whether the introduction into their return front by Messrs. STARK & LINDSAY of almost an exact reflection of the central mass of their principal façade is, we will not say necessary, or even desirable, but, on true critical grounds, admissible? For one thing, does not such treatment at once suggest the third and fourth campanili?

Let anyone should suppose that we are following the vulgar rule of regarding criticism as mere fault-finding, let us here interpose our most cordial congratulations to Messrs. LEEMING upon their success artistically as well as otherwise; and let us say further that, in spite of all that has been complained of, we regard a full majority of the nine competitors to have acquitted themselves most honourably.

The next point to which we shall direct attention is the composition of the two chief façades, on the flat rather than in the solid. Messrs. LEEMING start with what we suppose no one will deny to be a graceful and well-proportioned "order," comprising basement, colonnade, and attic. Now if we may

be permitted to put ourselves in the place of the designers, we will venture to submit that the idea which first occurred to their minds was the display of an unbroken colonnade from campanile to campanile. But, such is the hold that a corrupt idea of the picturesque has taken upon English architectural taste, that they would be justified in concluding that such simplicity would be regarded as meagreness; and, in a word, what has been done, in order to "break up" the façade, is to convert it into a make-believe centre and wings by the expedient of forming two very original, perhaps, but perfectly unnecessary (as regards plan), and surely palpably spurious features, in which a pair of wall-turrets, with no possible object except display or dress, are supported behind by the pretence of a pavilion roof with no other object either. Not only so, but this gratuitous arrangement is reproduced on the flank wall. One special reason that may be assigned for all this is sky-line; but the difference between true and false sky-line could scarcely be better exemplified than in the contrast of this composition with Messrs. STARK & LINDSAY's. If such a master as the late Sir CHARLES BARRY had had the handling of this, we venture to say he would have discarded these pavilions of Messrs. LEEMING's, clever as they may be in their way, without a moment's hesitation; and if sky-line be in request, we frankly ask Messrs. LEEMING to consider whether it may not be obtained in a better and indeed easier way.

The graceful proportions of the "order" induce us to suggest that it is matter for regret that the entablatures should be so remorselessly broken as they are throughout. The reason for this is no doubt to be found in the same unhappy devotion to the picturesque at all hazards which has been already spoken of, and which, as a principle of artistic design, is simply ruinous to Classic architecture on a grand scale. A tyro can see at a glance that the effect of these broken entablatures is to produce a mere row of buttresses. Would it not be much better, especially if the pavilions were abandoned, to make one grand range of colonnade, basement, and attic, in the simple simplicity of the original Classic purpose of such features? It is only on paper that a broken entablature accomplishes its purpose; and a bad purpose it is at the best.

Are Messrs. LEEMING really serious in the design of their campanili? Originality is all very well, as precedent is all very well; but if their good taste can stomach, *inter alia*, the paltry French gablets which occupy the attic stage at the angles, how can they justify the pair of pilasters in the middle of the next stage, and the development above into a single narrow pier, to the end that the lantern and roof may, for a change, be turned round forty-five degrees from the square? Is this a Classic motive? Granted that paper piquancy may have been served by this unique mode of composition, may we not hope, now that the question is one of actual building, that all such whimsies will be reconsidered? No one, we venture to think, can say that we are here displaying anything like ungraciousness towards the clever new-comers who have taken the lead in this competition; we must beg of them to take our remarks as mere academical criticism, for the benefit, we do not presume to say of themselves, but of such of our readers as will take the trouble to follow them, and to whose individual judgment we submit them as a lesson, for what it is worth.

Another question worth raising for consideration is this:—Why so many peaks? The spurious piquancy of the hour, we submit again, and not Classical repose; a paper purpose again, and not a true structural effect. Surely it is good criticism to say that the fewer of these empty sky-line pinacles there are, the more classically chaste the *ensemble* will be. One of the most effective dogmas in architectural design of whatever sort is this—that everything should be occupied, and honestly occupied. A mediæval corner turret, for instance, say on the angle of a church tower, contains a stair, and even its rooflet, if carried up beyond, need not be empty and inaccessible. The tourelles of a grim old Scottish castle-keep were little chambers of utility, either for the lord's bowman or the lady's tiring-maid. To take an extreme instance, Messrs. LEEMING's lofty tower at the corner of the Horse Guards—although what æsthetic purpose it serves may be fairly made a question—need not at any rate be vacant, even in its uttermost height, so long as a fair lady can be asked to ascend within and gratify her curiosity by a bird's-eye view of the park and the river. Now what have Messrs. LEEMING got in the lantern stage of their corner campanili? Suppose the late Sir CHARLES BARRY were again advising them, and suppose he swept away,

as we have suggested, the pairs of empty little square face-turrets that are so picturesque on paper, let us ask plainly whether he would leave the lanterns of the campanili. Would not the effect of repose be all the better without them? What he would do, again, with the whole minaret in Whitehall we will only mention as another question to be asked.

Turning to Messrs. STARK & LINDSAY's design, we would ask in like manner whether the effect would not be improved by omitting the upper stage—very well designed as it is—of the corner towers?

The two designs before us may suggest, lastly, a consideration of the difficult critical question whether to prefer an order for each storey, with its comparative feebleness of effect, or an order of two storeys with its unquestionably greater resources in the direction of majesty and simplicity. It is a good primary principle, by the way, that every floor-level inside should be marked by a cornice or string-line outside. Thus, when a figure is seen at a window, the eye ought to see its base line in the architecture; and whenever, on the contrary, a cornice line is seen to cut off half the leg or to put the figure on stilts, the rule of the fitness of things seems to be violated.

Minor points we do not profess to touch upon, but if we have succeeded in leading the reader to think for himself upon a few general questions, we have fulfilled our promise. We hope to see Messrs. LEEMING improve their design in execution, so as to make it a great and noble work. If they wish to see an example of what may be done in this way, we recommend a comparison of the original design for the Houses of Parliament with the very much altered version of it which the genius of Sir CHARLES BARRY developed in execution.

One last word in a general sense. Remember the cynical advice given to young writers—to strike out all the best passages. The same advice may often be shrewdly given to architects, especially in these days of piquancy at any price.

### THE OXFORD PRIZE POEMS AND ARCHITECTURE.

ONE of the institutions at Oxford is the production of prize poems annually. In old days it was supposed that the poet was inspired, and therefore could chant or write only on those occasions when he was in a particular mood. But the university authorities have taken another view. As SWIFT was supposed to be able to write beautifully, with no better theme than a broomstick, and WARREN's poet was always ready to be tender on blacking, so it has been, and is still thought, that an university student should always be competent to make his eyes roll in a fine phrenzy about the prosiest subjects. It is not surprising, a joker said, that "prize poems are not prized poems," and that critics have blessed the memory of Sir ROGER NEWDEGATE for limiting the competition for his prize to fifty lines.
